1. Instanton determinant. In this problem we will calculate explicitly the ratio of determinants

$$
K^{\prime}=\frac{\operatorname{det}^{\prime}\left(-\frac{d^{2}}{d \tau^{2}}+V^{\prime \prime}(\bar{x}(\tau))\right)}{\operatorname{det}\left(-\frac{d^{2}}{d \tau^{2}}+1\right)}
$$

where a double well potential $V(x)$ reads: $V(x)=\kappa\left(a^{2}-x^{2}\right)^{2}$ with $\kappa=1 /\left(8 a^{2}\right)$. Prime at the determinant means that the zero eigenvalue (zero mode) is not included, by $\bar{x}(\tau)$ we denote classical trajectory.

- The eigenequation for quantum fluctuations around the classical trajectory (with $\tau_{1}=0$, where $\tau_{1}$ is the time when the classical trajectory passes through zero):

$$
\begin{equation*}
\left[-\frac{d^{2}}{d \tau^{2}}+V^{\prime \prime}(\bar{x}(\tau))\right] y_{n}(\tau)=\lambda_{n} y_{n}(\tau) \tag{1}
\end{equation*}
$$

corresponds to the Schrödinger equation for a potential $U(\tau)=-3 /\left(2 \cosh ^{2}(\tau / 2)\right)$ (where $\tau$ plays a role of a spacial variable) and energy $E_{n}=\lambda_{n}-1$, which is discussed in the "Quantum Mechanics" of Landau and Lifischitz (probl. 5 page. 81 and probl. 4 page 88, Polish edition PWN 1979).
Transform equation (1) into a hypergeometric equation for function $w_{n}$ defined below:

$$
y_{n}(\tau)=e^{\alpha \tau} w_{n}(\tau),
$$

where

$$
\alpha= \pm \sqrt{-E_{n}}, \quad E_{n}=\lambda_{n}-1 .
$$

Show that the solution reads:

$$
y_{n}(\tau)=\mathcal{N}\left(3 \tanh ^{2}\left(\frac{\tau}{2}\right)-6 \alpha \tanh \left(\frac{\tau}{2}\right)+\left(4 \alpha^{2}-1\right)\right) e^{\alpha \tau}
$$

To this end introduce the following new variables:

$$
\begin{aligned}
& z=\tanh \left(\frac{\tau}{2}\right) \\
& u=\frac{1}{2}(1+z)
\end{aligned}
$$

In terms of variable $u$ Eq.(1) corresponds to the hypergeometric equation

$$
u(1-u) w^{\prime \prime}(u)+\{c-(a+b+1) u\} w^{\prime}(u)-a b w(u)=0,
$$

whose solutions are given in terms of a series

$$
w(u)=F(a, b, c ; u)=1+\frac{a b}{c} \frac{u}{1!}+\frac{a(a+1) b(b+1)}{c(c+1)} \frac{u^{2}}{2!}+\ldots
$$

- Find discrete spectrum of the bound states $(E<0)$ for $(1)$. Conditions that solutions vanish at $\tau= \pm \infty$ give quantization of $\alpha$.
- This part will be most probably shifted to next class. To find contribution from the continuous spectrum we show first that there is no reflection for the particles scattering over the potential $U(\tau)$. To this end find asymptotics for two types of the solutions: $\alpha=i k$ and $\alpha=-i k$ in the limit $\tau \rightarrow \pm \infty$.
- If there is no reflection then the wave function $y_{k}(\tau)$ that asymptotically behaves as $e^{i k \tau}$ for $\tau \rightarrow \infty$, in the limit of $\tau \rightarrow-\infty$ behaves as $e^{i k \tau+i \delta_{k}}$, where $\delta_{k}$ is a phase shift. Show that

$$
e^{i \delta_{k}}=\frac{1+i k}{1-i k} \frac{1+2 i k}{1-2 i k} .
$$

Identical argument applies to the wave function, that asymptotically behaves as $e^{-i k \tau}$.

- Close the system in a box $-T / 2<\tau<T / 2$. Then the wave function inside the box is a superposition of two linearly independent solutions

$$
y_{n}(\tau)=A y_{\alpha=i k}(\tau)+B y_{\alpha=-i k}(\tau)
$$

which vanishes at the boundaries

$$
\begin{equation*}
y_{n}( \pm T / 2)=0 . \tag{2}
\end{equation*}
$$

If the box is large, it is enough to use asymptotic forms of $y_{\alpha= \pm i k}(\tau)$. Show that condition (2) leads to

$$
T k-\delta_{k}=\pi n
$$

Let's denote solution to this equation by $\tilde{k}_{n}$. Similarly, for the Euclidean harmonic oscillator analogous solutions read $k_{n}=\pi n / T$.

- The contribution to $K^{\prime}$ coming from the continuous spectrum, $K_{\text {cont }}$, reads:

$$
K_{\text {cont }}=\frac{\prod \tilde{\lambda}_{n}}{\prod \lambda_{n}}=\prod_{n=1}^{\infty} \frac{1+\tilde{k}_{n}^{2}}{1+k_{n}^{2}}=\exp \left(\sum_{n} \ln \frac{1+\tilde{k}_{n}^{2}}{1+k_{n}^{2}}\right) \approx \exp \left(\sum_{n} \frac{2 k_{n}\left(\tilde{k}_{n}-k_{n}\right)}{1+k_{n}^{2}}\right) .
$$

- To calculate last sum under exponent go to the continuum limit $T \rightarrow \infty$ and convert the sum into the integral:

$$
\ldots=\exp \left(\frac{1}{\pi} \int_{0}^{\infty} d k \frac{2 \delta_{k} k}{1+k^{2}}\right)=\frac{1}{9} .
$$

Last equality can be obtained by integration by parts and the explicit form of $\delta_{k}$. Full result for $K^{\prime}$ is obtained by multiplying $K_{\text {cont }}$ by a non-zero $\lambda$ value from the discrete part.
