Lectures, Zakopane June 2011

Evolution of the Early Universe

QCD Phase Boundary

Homogeneous Universe in Equilibrium, this matter can only be investigated in nuclear collisions

- Charge neutrality
- Net lepton number = net baryon number
- Constant entropy/baryon

neutrinos decouple and light nuclei begin to be formed

the QCD phase diagram

Andronic et al., arXiv:0911.4806
Nucl. Phys. A837 (2010) 65

data points:
'chemical' freeze-out of hadrons

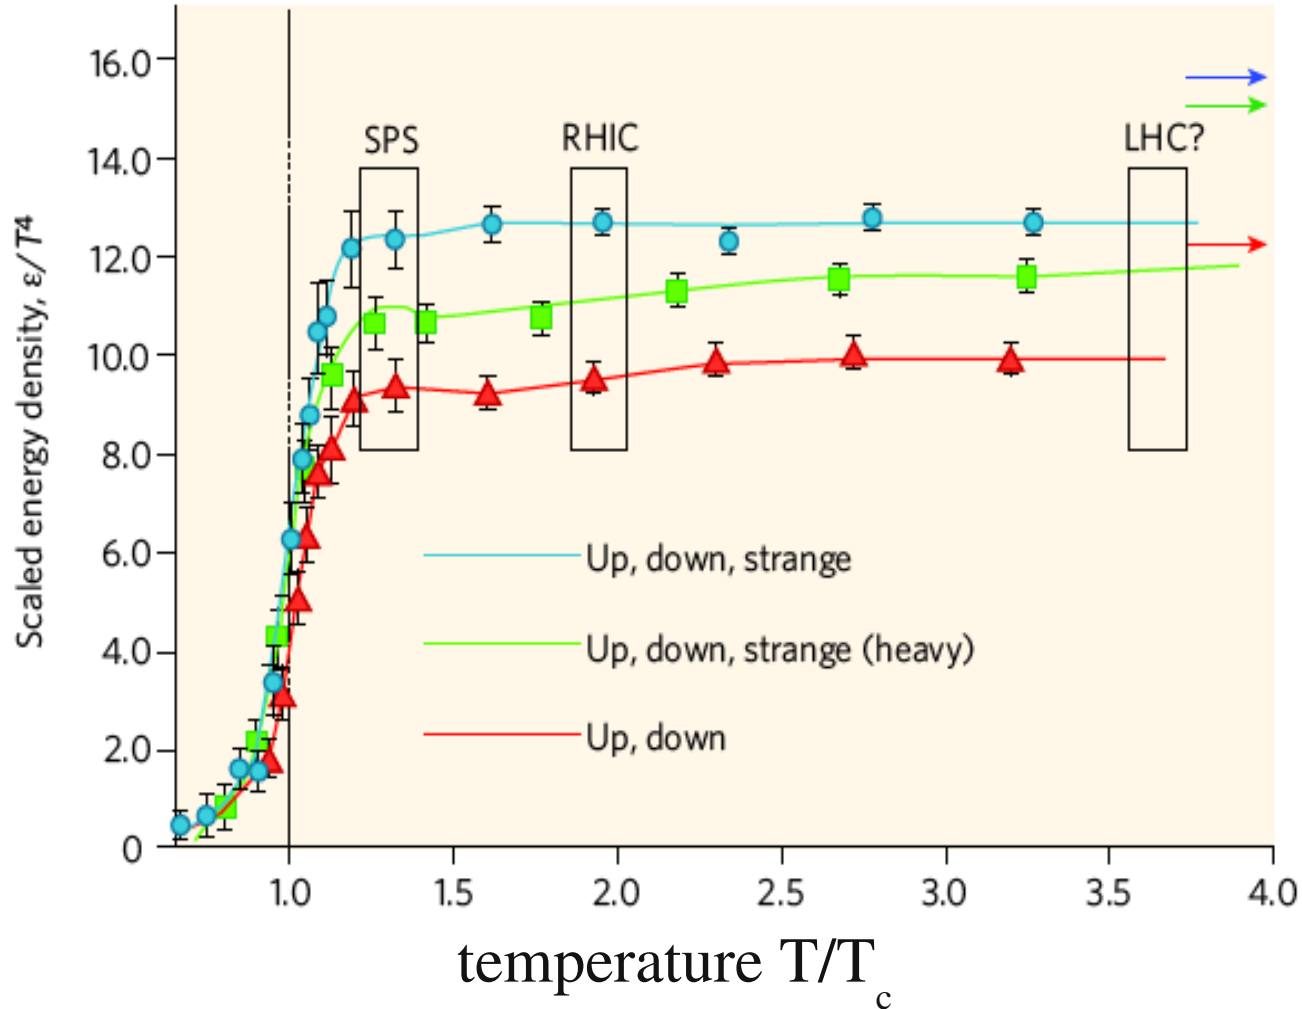

all lattice groups now agree: $T_c(\mu=0)$ is close to 170 MeV

The Space-Time Evolution of a Relativistic Nuclear Collision at LHC Energy

one possible view
(courtesy
Larry McLerran)

Charmonium as a probe for the properties of the QGP

the main idea: implant charmonia into the QGP and observe their modification, in terms of suppressed (or enhanced) production in nucleus-nucleus collisions with or without plasma formation

recent reviews: L. Kluberg and H. Satz, arXiv:0901.3831

pbm and J. Stachel, arXiv:0901.2500

both published in Landoldt-Boernstein Review, R. Stock, editor, Springer 2010

time scales

for this picture to hold, the following time sequence is needed:

- 1) charmonium formation
- 2) quark-gluon plasma (QGP) formation
- 3) melting of charmonium in the QGP
- 4) decay of remaining charmonia and detection

questions:

- a) beam energy dependence of time scales
- b) what happens with the (many) charm quarks at hadronization, i.e at the phase boundary?

energy dependence of charmonium production

Survival of Quarkonia in the QGP

new development:
 J/ψ does not survive above T_c

predicted quarkonium dissociation temperatures
in the QGP

A. Mocsy & P. Petreczky, Phys. Rev. Lett. 99 (2007) 211602

expect all charmonia to be destroyed
by QGP

but: regeneration at the phase boundary!

Hadronization of charm quarks – a special case?

If charmonium survives beyond T_c in the quark-gluon plasma, this implies in return that charm quarks hadronize at $T > T_c$.

The concept of a phase boundary between hadronic matter and quark-gluon plasma implies conversion of partons into hadrons within the (cross over?) transition.

A flavor-dependent phase boundary calls the whole concept of the deconfinement phase transition into question.

Remarks on production of open charm and charmonia

- charm quark mass $\gg \Lambda_{\text{QCD}}$ production described in QCD perturbation theory
- all calculations employ gluon fusion as starting point
- argument is energy independent until global energy conservation very close to threshold becomes important
- production of charm quark pairs takes place at timescale $1/2m_c$
 $m_c = 1.3 \text{ GeV} \rightarrow t_c = 0.08 \text{ fm}$
- to build up wave function of mesons including those with open charm needs about $t = 1 \text{ fm} \rightarrow$ charm production and charmed hadron formation are decoupled
- overall cross section is due to production of charm quark pairs
- time scale is much too short to dress the charm quarks essential to take current quarks for production

open charm production in hadronic collisions

lowest order diagrams: gluon fusion (a,b) and annihilation (c)

charmonium production in hadronic collisions

color neutralization as additional step

J/psi/cc_bar cross section

about 1 % of cc_bar pairs end up in J/psi

variation reflects uncertainty in open charm cross section?

→ at hadronization 99% of initial charm quarks are still there

More timescales

formation and destruction of J/ψ (charmed hadrons)

- QGP formation time, t_{QGP}
 - FAIR, SPS: $t_{QGP} \simeq 1 \text{ fm}/c \sim t_{J/\psi}$
 - RHIC, LHC: $t_{QGP} \lesssim 0.1 \text{ fm}/c \sim t_{c\bar{c}}$

survival of initially-produced J/ψ at FAIR/SPS energies? ($T_d \sim T_c$)

- collision time, $t_{coll} = 2R/\gamma_{cm}$
 - FAIR, SPS: $t_{coll} \gtrsim t_{J/\psi}$
 - RHIC: $t_{coll} < t_{J/\psi}$, LHC: $t_{coll} \ll t_{J/\psi}$

cold nuclear suppression important at FAIR/SPS energies?

full separation of time scales at LHC energy

At collider energies there will be yet another separation of time scales. At LHC energy, the momentum of a Pb nucleus is $p_{cm}=2.76$ TeV per nucleon, leading to $\gamma_{cm} = 2940$, hence $t_{coll} < 5 \cdot 10^{-3}$ fm. Even “wee” partons with momentum fraction³ $x_w = 2.5 \cdot 10^{-4}$ will pass by within a time $t_w = 1/(xp_{cm}) < 0.3$ fm, and will not destroy any charmonia since none exist at that time. We consequently expect that cold nuclear absorption will decrease from SPS to RHIC energy and should be negligible at LHC energy. First indications for this trend are visible in the PHENIX data [22].

Role of cold nuclear matter effects

what is it:

destruction of charmonia by colliding nuclei before QGP formation

- may be important at SPS and lower energies
- charmonium formation time long compared to QGP formation time, especially at LHC --> **no cold nuclear matter effects at LHC**

what it is not:

rapidity dependent reduction of charm and charmonium production due to shadowing or saturation
energy loss effects

A. Andronic et al., Nucl. Phys. A709 (2007) 334
standard view of CNM effects, see R. Vogt, arXiv:1003.3497

Energy dependence of J/ψ absorption cross section

C. Lourenco, R. Vogt, H. Woehri
 JHEP 0902 (2009) 014
 arXiv:0901.3054 [hep-ph]

$\text{sig_abs} = 5.8 - 11.5 \text{ mb}$
 depending on shadowing

Role of non-QGP effects

investigation of 'anomalous' charmonium production in AA collisions

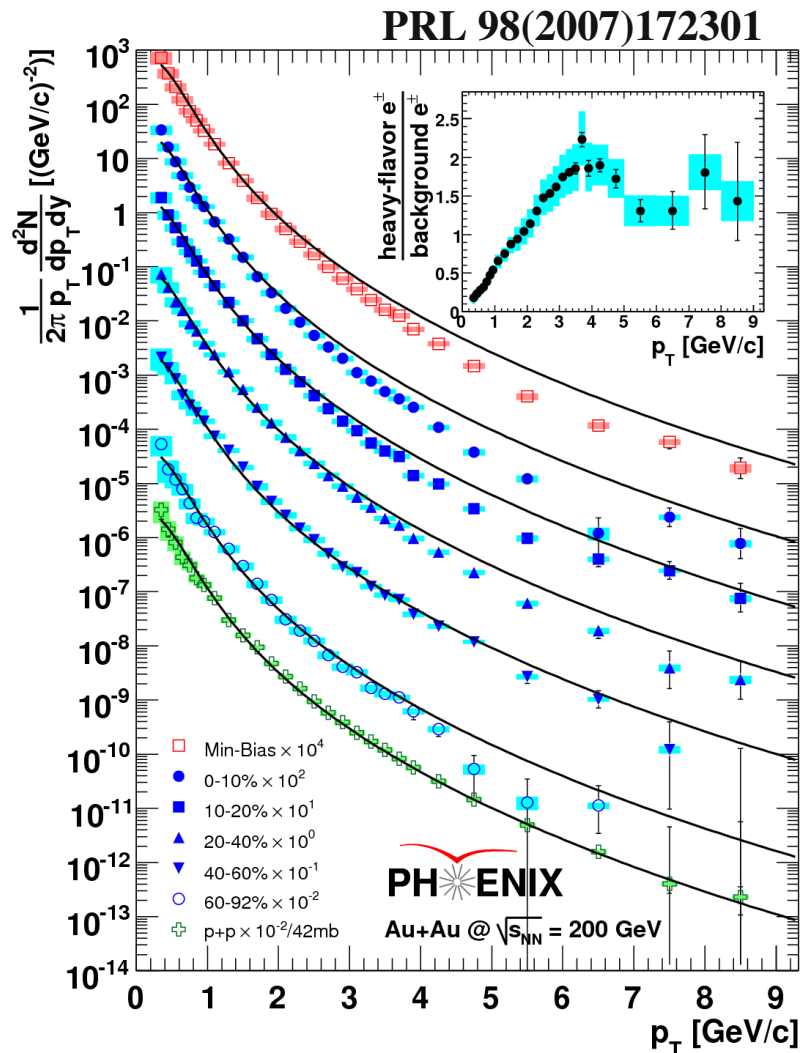

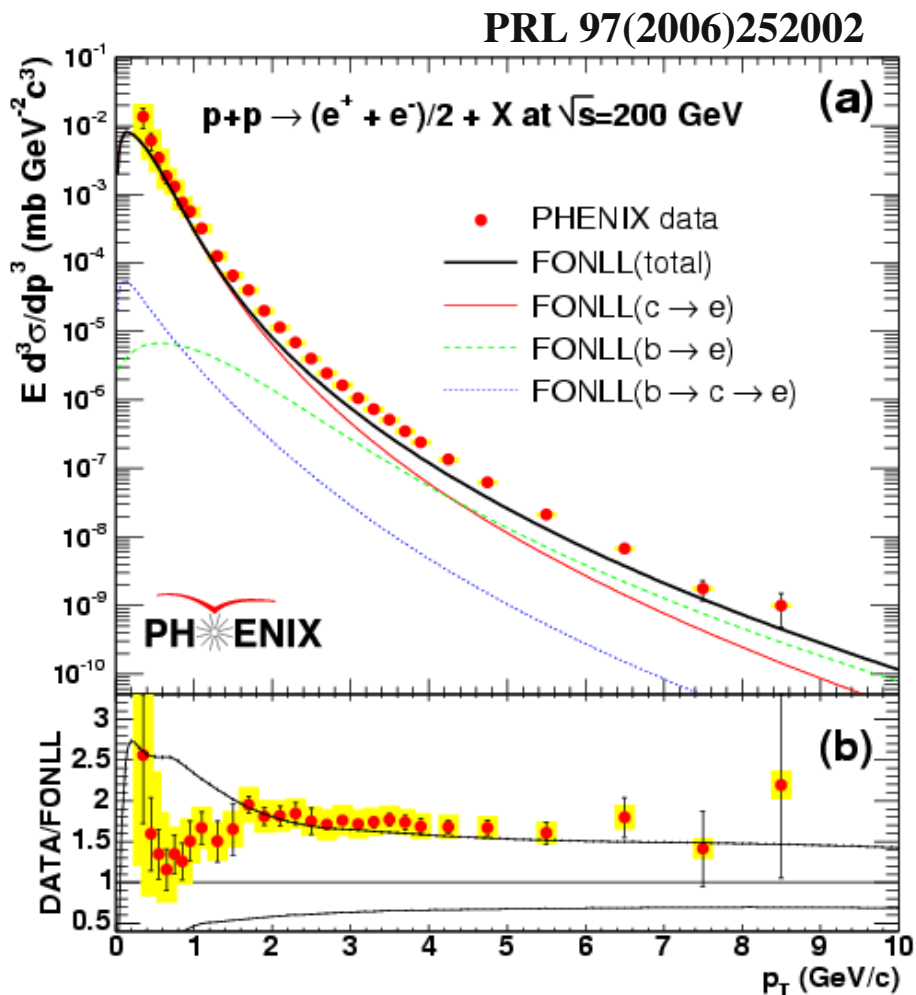

need to normalize charmonium production to open charm cross section in AA collisions for given centrality

pp and pA collisions are useful to study possible shadowing or saturation effects, not for charmonium suppression or enhancement in the QGP

actually, the pA or dA baseline is questionable at LHC because of thermal production of charm quarks (K. Redlich and pbm, Eur. J. Phys. C16 (2000) 334)

is there any evidence for saturation or shadowing from RHIC data?? $\sigma_{cc\bar{c}}(AA) = N_{\text{coll}} \sigma_{cc\bar{c}}(pp)$??

PHENIX data on charm cross section

PHENIX open charm cross section is close to pQCD prediction
 STAR value was about a factor of 2 larger ... now resolved (material)
 need vertex detectors! But no evidence for shadowing so far.
 This is an area for LHC!!! See later.

A brief digression: the fireball emits hadrons from an equilibrium state

- From low AGS energy on, all hadron yields in central PbPb collisions reflect grand-canonical equilibration
- Strangeness suppression observed in elementary collisions is lifted
- Equilibration at SIS energy?

how do we get information on the phase boundary?

For a recent review see:

QGP3, R. Hwa, editor,
Singapore 2004,
nucl-th/0304013

Hadro-chemistry at RHIC -- weakly decaying particles

All data in excellent agreement with thermal model predictions

chemical freeze-out at: $T = 165 \pm 8$ MeV

fit uses vacuum masses

most recent analysis:

A. Andronic, pbm, J.

Stachel,

nucl-th/0511071

Nucl. Phys.

A772(2006) 167

pbm, d. magestro, j. stachel, k. redlich,
 Phys. Lett. B518 (2001) 41; see also Xu et al., Nucl.
 Phys. A698(2002) 306; Becattini, J. Phys. G28 (2002)
 1553; Broniowski et al., nucl-th/0212052.

Fit to STAR data alone

very good fit, even including strongly decaying resonances

no evidence for special role of wide states

... but, in general, fits are not perfect

for example, PHENIX protons are significantly below the model results

Are charmonia (and charmed hadrons) produced thermally?

ratios of charmed and beauty hadrons exhibit thermal features (Becattini 1997)
but: $(J/\psi)/\psi'$ ratio is far from thermal in $e+e-$ and pp collisions
see also Sorge&Shuryak, Phys. Rev. Lett. 79 (1997) 2775, where it is further
noted that the $(J/\psi)/\psi'$ ratio reaches a thermal value ($T=170$ MeV) in central
PbPb collisions at SPS energy

further analysis by Gorenstein and Gazdzicki, Phys. Rev. Lett. 83 (1999) 4003
result: $(J/\psi)/\pi$ is approximately constant at SPS energy for PbPb

However, thermal production of charm quarks is appreciable
only at very high temperatures (LHC)
($T > 800$ MeV, pbm&Redlich, Eur. Phys. J. C16 (2000) 519).

solution: charm quarks produced in hard collisions, then statistical
hadronization at the phase boundary.

Energy loss and flow of heavy quarks

charm quark flow and large energy loss imply approach to thermal but not chemical equilibrium

new ALICE results for HF electrons and D mesons discussed below

Transverse Momentum Distributions

**no strong broadening observed as expected
for initial state scattering**

this is different from the situation at the SPS

The ψ'/ψ ratio in elementary and AA collisions

Summary of this part

- charmonium production very different in elementary and AA collisions
- charm quark production mainly non-thermal
- at collider energies, charmonia are formed late, QGP is earlier
- no serious evidence for hadrons formed or surviving in the QGP
 - charmonia are formed at the phase boundary like all other hadrons
 - statistical hadronization model

Charmonium (re)generation models

- statistical hadronization model

original proposal: pbm, J. Stachel, Phys. Lett. B490 (2000) 196

assumptions:

- all charm quarks are produced in hard collisions, N_c const. in QGP
- all charmonia are dissolved in QGP or not produced before QGP
- charmonium production takes place at the phase boundary with statistical weights
→ yield $\sim N_c^2$ -- quarkonium enhancement at high energies
-- no feeding from higher charmonia

- charm quark coalescence model

original proposal: R.L. Thews, M. Schroedter, J. Rafelski, Phys. Rev. C63 (2001) 054905

assumptions:

- all charm quarks are produced in hard collisions
- all charmonia are produced in the QGP via charm quark recombination

→ yield $\sim N_c^2$ -- quarkonium enhancement at high energies

Method and inputs

Thermal model calculation (grand canonical) $T, \mu_B: \rightarrow n_X^{th}$

$$N_{c\bar{c}}^{dir} = \frac{1}{2} g_c V (\sum_i n_{D_i}^{th} + n_{\Lambda_i}^{th}) + g_c^2 V (\sum_i n_{\psi_i}^{th} + n_{\chi_i}^{th})$$

$N_{c\bar{c}} \ll 1 \rightarrow$ **Canonical:** J.Cleymans, K.Redlich, E.Suhonen, Z. Phys. C51 (1991) 137

charm balance
equation

$$N_{c\bar{c}}^{dir} = \frac{1}{2} g_c N_{oc}^{th} \frac{I_1(g_c N_{oc}^{th})}{I_0(g_c N_{oc}^{th})} + g_c^2 N_{c\bar{c}}^{th} \rightarrow g_c$$

Outcome: $N_D = g_c V n_D^{th} I_1/I_0$ $N_{J/\psi} = g_c^2 V n_{J/\psi}^{th}$

Inputs: $T, \mu_B, V = N_{ch}^{exp}/n_{ch}^{th}, N_{c\bar{c}}^{dir}$ (pQCD)

Parameterization of all freeze-out points

note: establishment of limiting temperature

$$T_{\text{lim}} = 160 \text{ MeV}$$

get T and μ_B for all energies

A. Andronic, pbm, J. Stachel,
Nucl. Phys. A772 (2006) 167
nucl-th/0511071

Ingredients for prediction of quarkonium and open charm cross sections

- energy dependence of temperature and baryo-chemical potential (from hadron production analysis)
- open charm (open bottom) cross section in pp and AA collisions
- quarkonium production cross section in pp collisions (for corona part)

result: quarkonium and open charm cross sections as function of energy, centrality, rapidity, and transverse momentum

important pre-requisite: all ratios among charmonia must be thermal

annihilation fraction

annihilation fraction
is less than 0.2 %,
even at LHC energy
and with $\alpha_s = 1$

results for SPS energy

only moderately enhanced (2 x pQCD) cc_{bar} cross section needed

extrapolation to pp for ψ'/ψ ratio still problematic in the model,
 although intuitively clear

RHIC result: nuclear modification factor

data exhibit strong centrality dependence and suppression, well described by our regeneration model without any new parameters

Comparison of model predictions to RHIC data: rapidity dependence

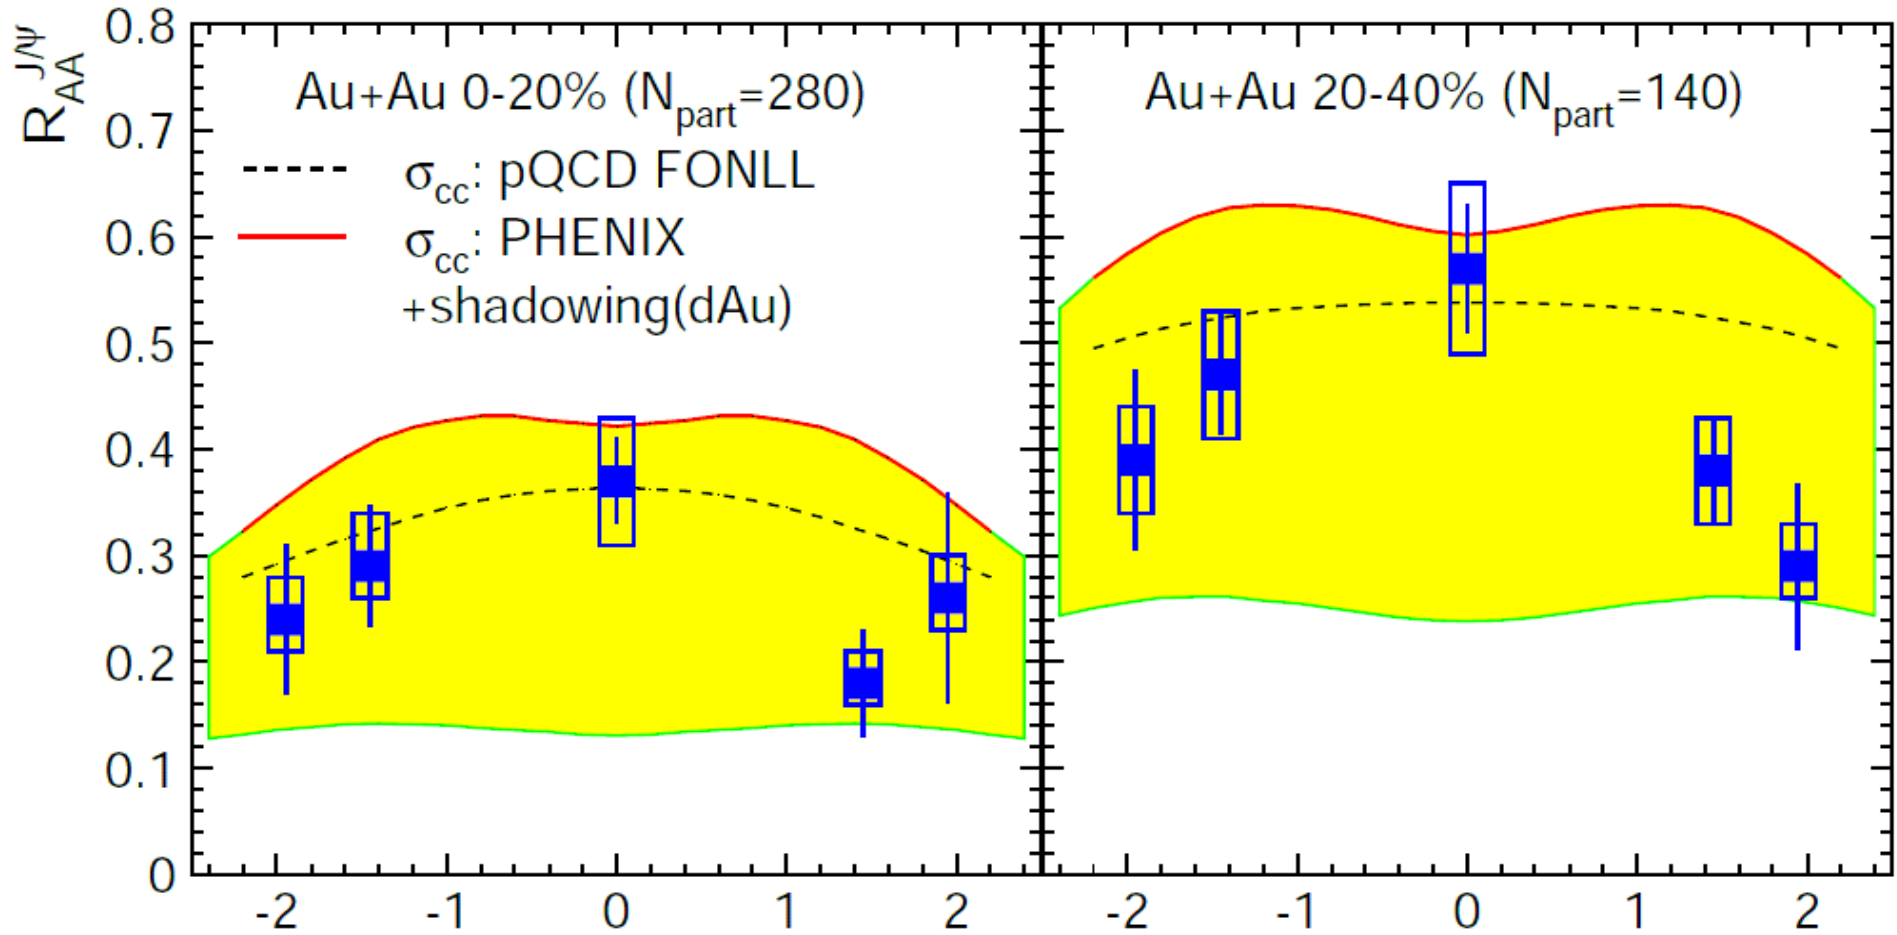

suppression is smallest at mid-rapidity (90 deg. emission)
a clear indication for regeneration at the phase boundary

Calculations including shadowing

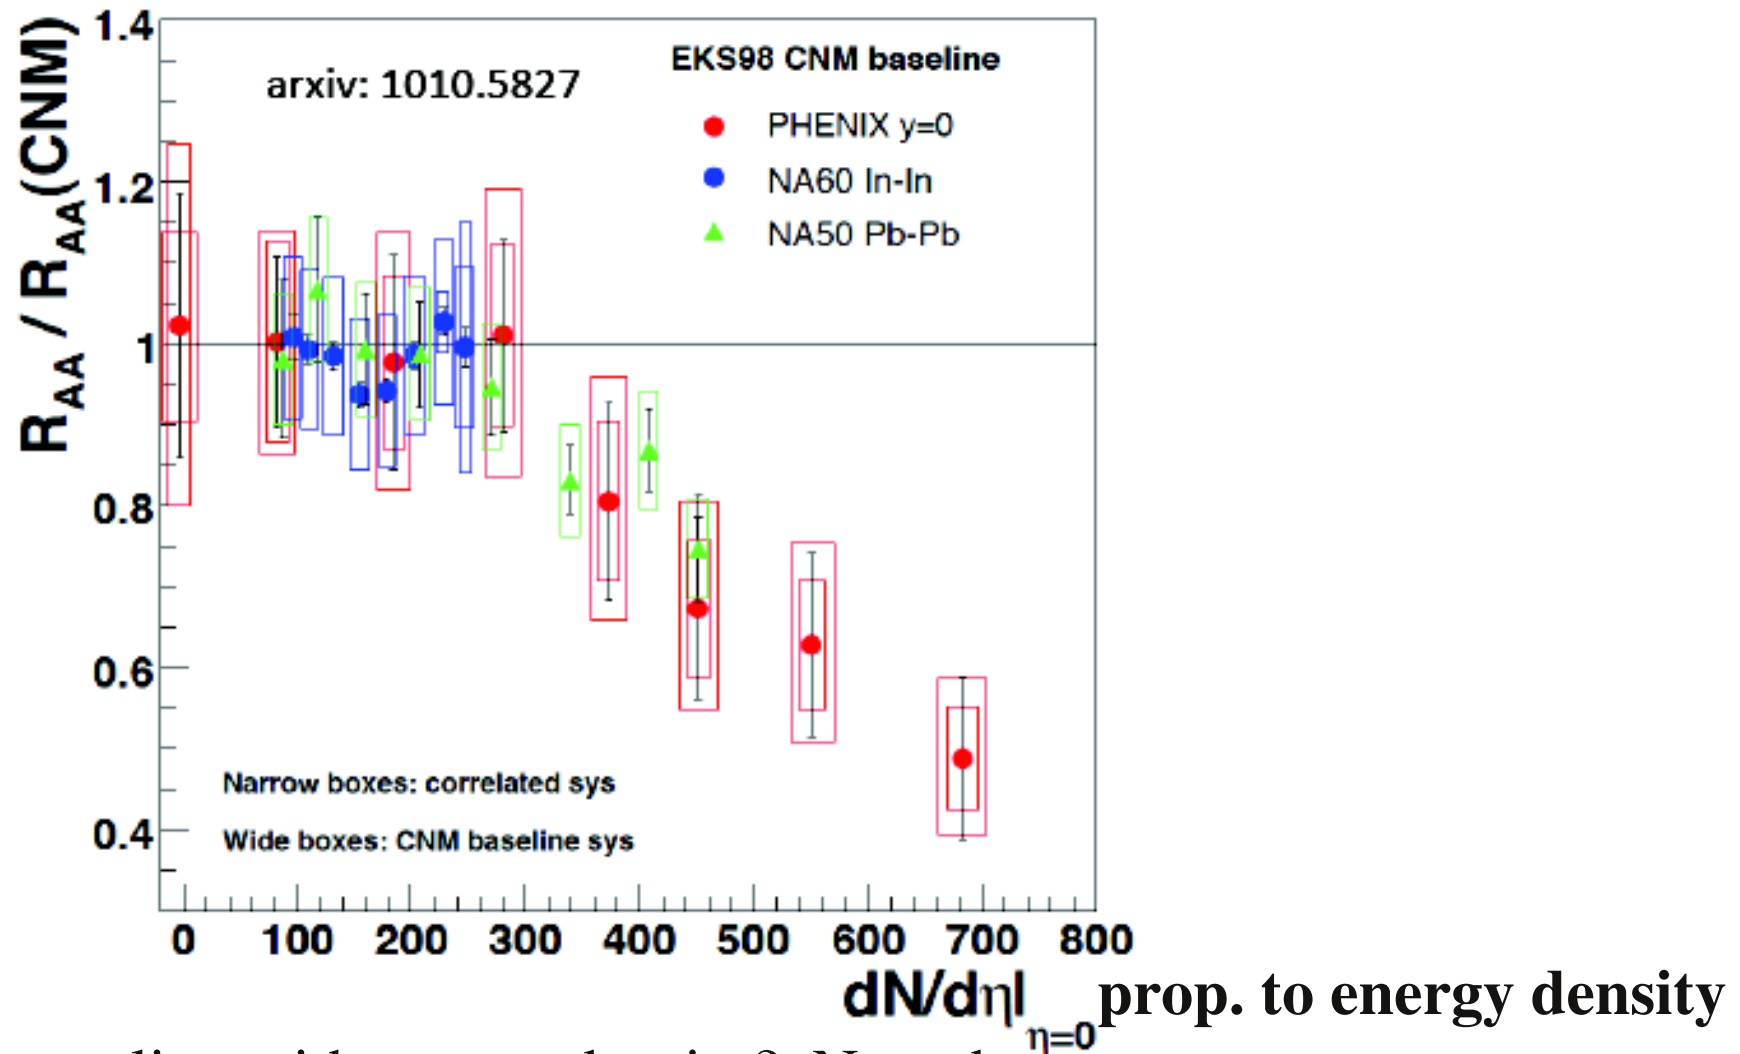

andronic, pbm, redlich, stachel

J. Phys. G37 (2010) 094014, arXiv:1002.4441 [nucl-th]

assume PHENIX pA data reflect shadowing
consistent with most recent PHENIX analysis
by Frawley et al.

summary of all pre-LHC data on J/psi production in AA collisions

Is there scaling with energy density? Note that $dN/d\eta = 1600$ at LHC energy ($y=0$)

EKS09 shadowing for J/psi production at LHC

At LHC energy, shadowing reduces R_{AA} significantly, but the exact amount needs to be determined, need open charm cross section in PbPb. Note also the centrality dependence!

An attempt to look at near threshold production

- charm cross section unknown
- but: $N_{ccbar} \ll 1$: only diagonal terms in recombination
- independent of energy, charm production still a hard process

Extrapolation of pQCD cross section to low energies

charm threshold
in NN: 5.1 GeV

absolute threshold
in Pb-Pb
collisions:

$$T_{\text{lab}}/A = 31 \text{ MeV}$$

Summary

- charmonium production – a fingerprint for deconfined quarks and gluons
- evidence for energy loss and flow of charm quarks --> thermalization
- normalization to open charm in AA collisions – pA or dA normalization not easily applicable at LHC
- charmonium generation at the phase boundary – a new process
- first indications for this from RHIC data
- no evidence for new physics near threshold
- charmonium enhancement at LHC – deconfined QGP still work to do but clear indications from J/psi
