## Outline

- CDT basics
  - CDT assumptions
  - Numerical setup
  - Summary of previous results
- Motivation
- The transfer matrix idea
  - Assumptions
  - Measurement
- Transfer matrix for large volumes
  - The effective action
  - Kinetic term
  - Potential term
  - Parameters of the action
- Transfer Matrix for small volumes
- Conclusions

### CDT basics

Motivation

The transfer matrix idea

Transfer matrix for large volumes

Transfer matrix for small volumes

### CDT assumptions

Numerical setup

Summary of previous results

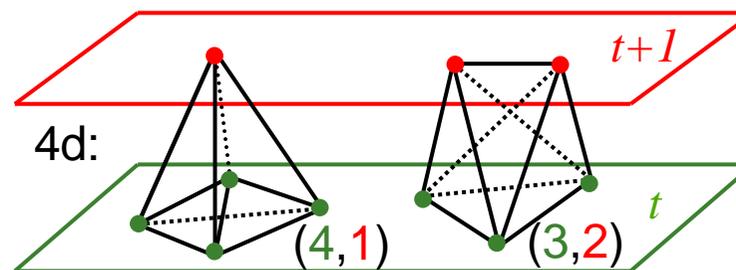

- **Causal Dynamical Triangulations (CDT)** is a non-perturbative approach to Quantum Gravity based on the path integral

$$Z = \int_{Geom} D[g] \exp(iS_{HE}[g])$$

- Regularization of  $Z$  is done by summing over all **causal triangulations**  $T$  constructed from 4-d simplices

$$Z = \sum_T \frac{1}{C_T} \exp(i\tilde{S}_R[T])$$

- We assume a **global time foliation**  $S^1$  and **fixed spatial topology**  $S^3 \Rightarrow$  resulting space-time  $S^1 \times S^3$  can be built from two types of simplices

**CDT basics****Motivation**

The transfer matrix idea

Transfer matrix for large volumes

Transfer matrix for small volumes

**CDT assumptions****Numerical setup**

Summary of previous results

- The Einstein-Hilbert action:

$$S_{HE} = \frac{1}{16\pi G} \int d^4x \sqrt{-g} (R - 2\Lambda)$$

- $G$  – Newton’s constant
- $g$  – metric determinant
- $R$  – curvature scalar
- $\Lambda$  – cosmological constant

- is regularized by the Regge action where curvature  $R$  is determined by the deficit angle „around” 2-d triangles

$$\tilde{S}_R = i \left[ \underbrace{-k_0}_{1/G} N_0 + \underbrace{K_4}_{\Lambda} N_4 + \underbrace{\Delta}_{\alpha} \left( N_4^{(4,1)} - 6N_0 \right) \right] = iS_R$$

$(l_t^2 = -\alpha l_s^2)$

- $N_0$  – # of vertices
- $N_4$  – # of 4-simplices
- $N_4^{(4,1)}$  – # of (4,1) & (1,4) simplices

- After Wick rotation:  $\alpha \rightarrow -\alpha$  ( $|\alpha| > 7/12$ )  $S_R$  is purely real:

$$Z = \sum_T \frac{1}{C_T} \exp(i\tilde{S}_R[T]) = \sum_T \frac{1}{C_T} \exp(-S_R[T]) \rightarrow \text{probability distribution}$$

## CDT basics

### Motivation

The transfer matrix idea  
Transfer matrix for large volumes  
Transfer matrix for small volumes

## CDT assumptions

### Numerical setup

Summary of previous results

Triangulations are updated dynamically by **Monte Carlo** methods

### ■ Alexander moves ...

□ preserve global & local topology  $\Leftrightarrow$  **causality**

□ any triangulation is achievable by a sequence of moves  $\Leftrightarrow$  **ergodicity**

■ ...are performed with probability determined by a **detailed balance condition**:

$$P(T_1)P(T_1 \xrightarrow{M} T_2) = P(T_2)P(T_2 \xrightarrow{M^*} T_1)$$

■ Monte Carlo simulations allow to compute probability distributions (histograms) of **observables**:

$$P(O) = \frac{1}{Z} \sum_{T(O)} \frac{1}{C_T} \exp(-S_R[T])$$

■ We focus on the distribution of the **spatial volumes of the universe** in different time slices:

$$O \equiv n_t = N_4^{(4,1)}(t) \propto V_3(t)$$

**CDT basics**

Motivation

The transfer matrix idea

Transfer matrix for large volumes

Transfer matrix for small volumes

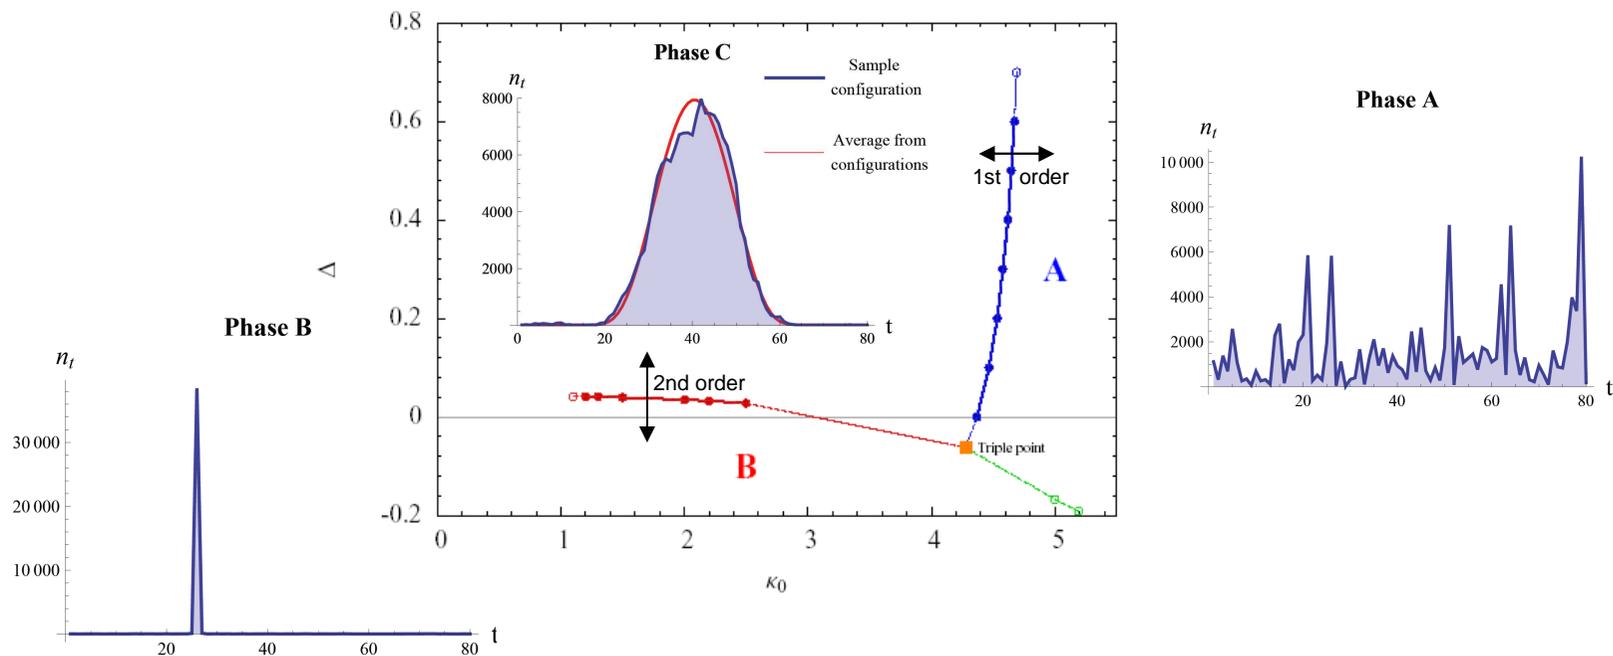

**CDT assumptions**

Numerical setup

**Summary of previous results**

$$S_R = -k_0 N_0 + K_4 N_4 + \Delta (N_4^{(4,1)} - 6N_0)$$

- Depending on the values of bare couplings  $k_0$  and  $\Delta$  ( $K_4 \approx K_4^{crit}$ ) **three phases** emerge

**CDT basics**

Motivation

The transfer matrix idea

Transfer matrix for large volumes

Transfer matrix for small volumes

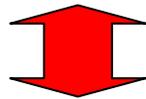

**CDT assumptions**

Numerical setup

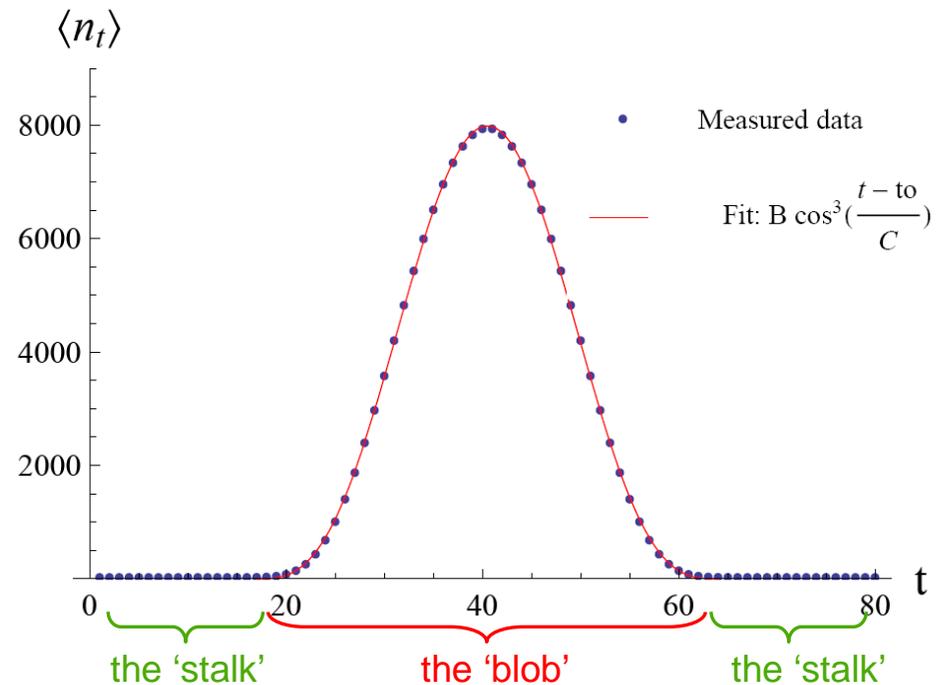

**Summary of previous results**

- In phase 'C' the dynamically generated semi-classical background ...

$$\langle n_t \rangle = \frac{3}{4} \tilde{V}_4 \frac{1}{\tilde{A} \tilde{V}_4^{1/4}} \cos^3 \left( \frac{t-t_0}{\tilde{A} \tilde{V}_4^{1/4}} \right)$$

$$\sqrt{g_{tt}} V_3(t) = \frac{3}{4} V_4 \frac{1}{A V_4^{1/4}} \cos^3 \left( \frac{t-t_0}{A V_4^{1/4}} \right)$$

- The solution (in the 'blob') is consistent with the Euclidean (Wick's rotation) **de Sitter Universe** (no matter, positive cosmological constant)

**CDT basics****Motivation**

The transfer matrix idea

Transfer matrix for large volumes

Transfer matrix for small volumes

**CDT assumptions****Numerical setup****Summary of previous results**

- ... and quantum fluctuations are governed by the action:

$$S = \frac{1}{24\pi G} \int dt \sqrt{g_{tt}} \left( \frac{g^{tt} \dot{V}_3(t)^2}{V_3(t)} + \mu V_3(t)^{1/3} - \lambda V_3(t) \right)$$

$$\square \mu = 9 \left( \frac{3}{4} \right)^{2/3} A^{-8/3} \quad \square \lambda = 9 V_4^{-1/2} A^{-2}$$

- This is the (Euclidean) **minisuperspace** (MS) action obtained from  $S_{HE}$  for the maximally symmetric metric:  $ds^2 = g_{tt} dt^2 + a^2(t) d\Omega_3^2$
- **CDT conjecture:** the effective action in the phase 'C' is a discretization of the minisuperspace action:

$$S_{dis} = \frac{1}{\Gamma} \sum_t \left( \frac{(n_{t+1} - n_t)^2}{n_{t+1} + n_t} + \tilde{\mu} n_t^{1/3} - \tilde{\lambda} n_t + O(n_t^{-1/3}) \right)$$

**CDT basics**

Motivation

The transfer matrix idea

Transfer matrix for large volumes

Transfer matrix for small volumes

**CDT assumptions**

Numerical setup

**Summary of previous results**

$$S_{dis} = \sum_t \frac{1}{\Gamma} \left( \underbrace{\frac{(n_{t+1} - n_t)^2}{n_{t+1} + n_t}}_{\text{kinetic part}} + \underbrace{\tilde{\mu}n_t^{1/3} - \tilde{\lambda}n_t}_{\text{potential part}} \right)$$

- Second order expansion of  $S_{dis}$  around semi-classical solution  $\bar{n}$

$$S_{dis}[\bar{n} + \delta n] = S_{dis}[\bar{n}] + \frac{1}{2} \sum_{t,t'} \delta n_t P_{tt'} \delta n_{t'} + O(\delta n^3)$$

can be compared with the covariance of volume fluctuations:  $C(\delta n_t, \delta n_{t'})$

$$P = P_{kin} + P_{pot} = C^{-1}$$

## CDT basics

### Motivation

#### The transfer matrix idea

#### Transfer matrix for large volumes

#### Transfer matrix for small volumes

### Motivation:

- The ‘blob’ range in phase ‘C’ is described by the MS effective action:
  - How good is this description ?
  - Can we measure the effective action directly (not only its 2<sup>nd</sup> derivative around  $\bar{n}$ ) ?
- How to describe the behaviour of the ‘stalk’ range ?
  - Average spatial volume in the ‘stalk’ does not scale with total 4-volume
  - Small volume discretization effects
  - Relatively large quantum fluctuations
- ‘Cleaning’ of discretization artifacts might lead to discovery of some non-trivial physical effects in the ‘tail’ (small volume) region
  - $P_{kin} \sim n^{-1}$
  - $P_{pot} \sim n^{-5/3}$

The transfer matrix idea

Transfer matrix for large volumes  
Transfer matrix for small volumes

$$S_{blob} = \sum_t \frac{1}{\Gamma} \left( \frac{(n_{t+1} - n_t)^2}{n_{t+1} + n_t} + \tilde{\mu} n_t^{1/3} - \tilde{\lambda} n_t \right) = \sum_t L_{blob}(n_t, n_{t+1})$$

$$\langle n_t | M_{blob} | n_{t+1} \rangle = \exp[-L_{blob}(n_t, n_{t+1})]$$

$$Z_{blob} = \sum_{n_1 \dots n_t \dots n_T} \exp(-S_{blob}) = \text{Tr}(M_{blob}^T)$$

Assumptions:

- we consider only effective aggregate ‘states’  $|n_t\rangle$
- description by the transfer matrix is also viable in the ‘stalk’ range
- identical probability distributions for all slices in ‘stalk’ range  $\Rightarrow M$  ~~(\*)~~
- time reflection symmetry  $\Rightarrow \langle n_t | M | n_{t+1} \rangle = \langle n_{t+1} | M | n_t \rangle$

The transfer matrix idea  
Transfer matrix for large volumes  
Transfer matrix for small volumes

$$Z = \sum_{n_1 \dots n_T} \prod_{t=1}^T \langle n_t | M | n_{t+1} \rangle = \text{Tr}(M^T)$$

- 1-point probability distribution:

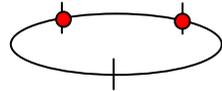

$$P_1^{(T)}(n) = \frac{1}{Z} \langle n | M^T | n \rangle$$

- 2-point probability distribution:

$$P_2^{(T, \Delta t)}(n, m) = \frac{1}{Z} \langle n | M^{\Delta t} | m \rangle \langle m | M^{T-\Delta t} | n \rangle$$

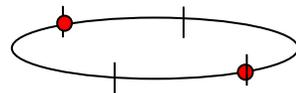

- Measured probabilities:

- $T = 3, \Delta t = 1$

$$P_2^{(3,1)}(n, m) \propto \langle n | M | m \rangle \langle m | M^2 | n \rangle$$

- $T = 4, \Delta t = 2$

$$P_2^{(4,2)}(n, m) \propto \langle n | M^2 | m \rangle^2$$

- can be used to determine  $M$ :

$$\langle n | M | m \rangle = N \frac{P_2^{(3,1)}(n, m)}{\sqrt{P_2^{(4,2)}(n, m)}}$$

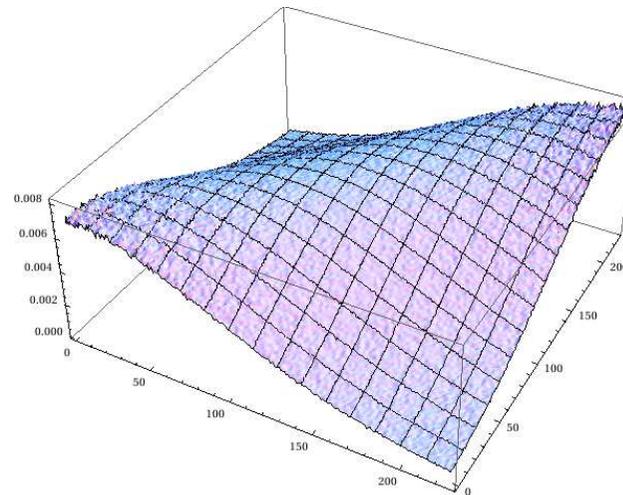

CDT basics  
 Motivation  
 The transfer matrix idea  
**Transfer matrix for large volumes**  
 Transfer matrix for small volumes

**The effective action**  
 Kinetic term  
 Potential term  
 Parameters of the action

- The effective action for large volumes (in the ‘blob’) is measured:

$$\langle n | M | m \rangle = N e^{-L_{eff}(n,m)}$$

$$L_{eff}(n,m) = \frac{1}{\Gamma} \left[ \frac{(n-m)^2}{n+m-2n_o} + \mu \left( \frac{n+m}{2} \right)^{1/3} - \lambda \left( \frac{n+m}{2} \right) \right]$$

CDT basics  
 Motivation  
 The transfer matrix idea  
**Transfer matrix for large volumes**  
 Transfer matrix for small volumes

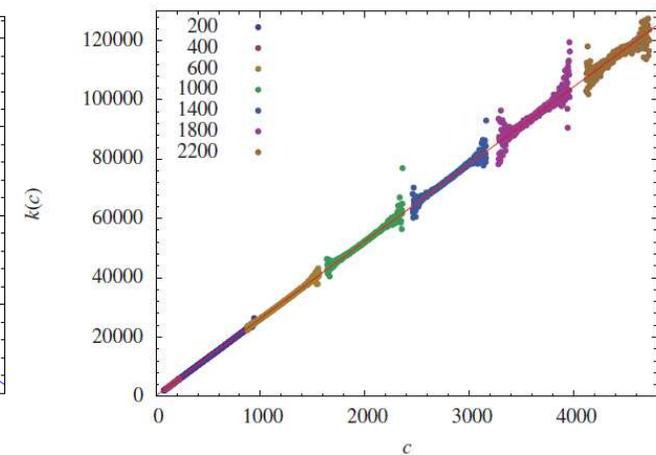

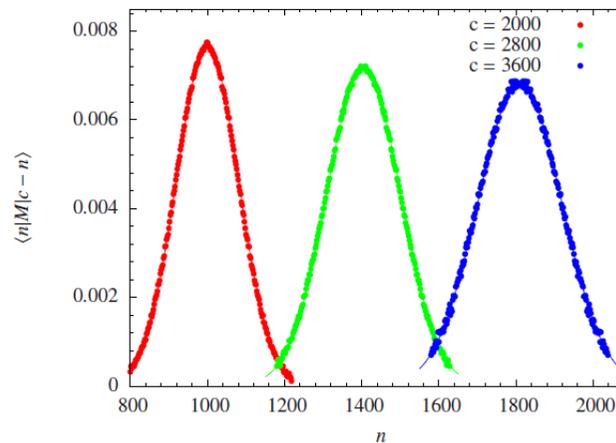

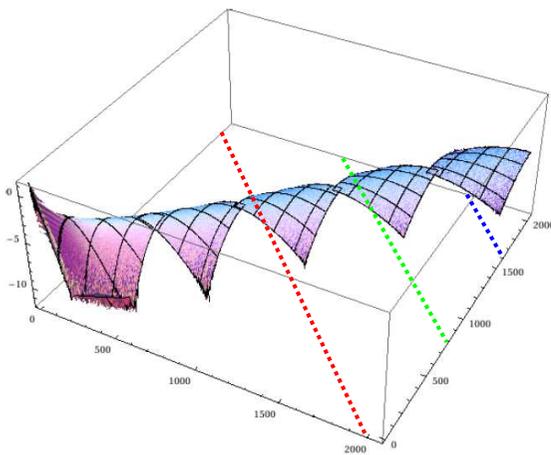

The effective action  
**Kinetic term**  
 Potential term  
 Parameters of the action

■ The kinetic term ...

$$\langle n | M | m \rangle = N e^{-\frac{1}{\Gamma} \left[ \frac{(n-m)^2}{n+m-2n_0} + \mu \left( \frac{n+m}{2} \right)^{1/3} - \lambda \left( \frac{n+m}{2} \right) \right]}$$

$k(n,m) = \Gamma (n+m-2n_0)$

□ Gaussian behaviour for  $n+m=c$ :  $\langle n | M | c-n \rangle = \tilde{N}(c) \exp \left[ -\frac{(2n-c)^2}{k(c)} \right]$

CDT basics  
 Motivation  
 The transfer matrix idea  
**Transfer matrix for large volumes**  
 Transfer matrix for small volumes

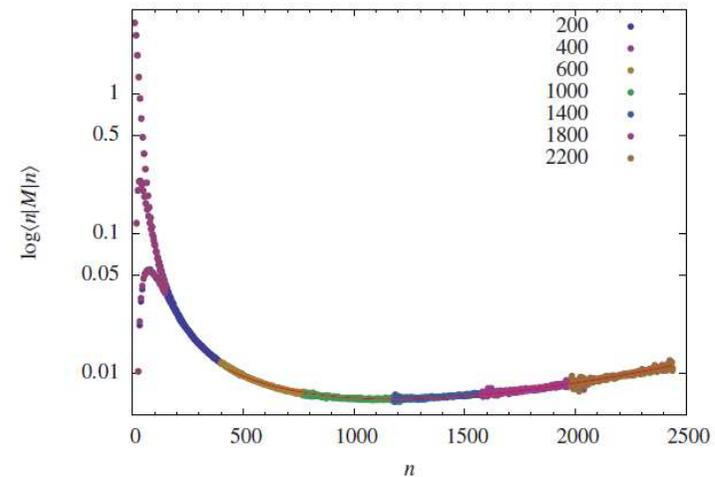

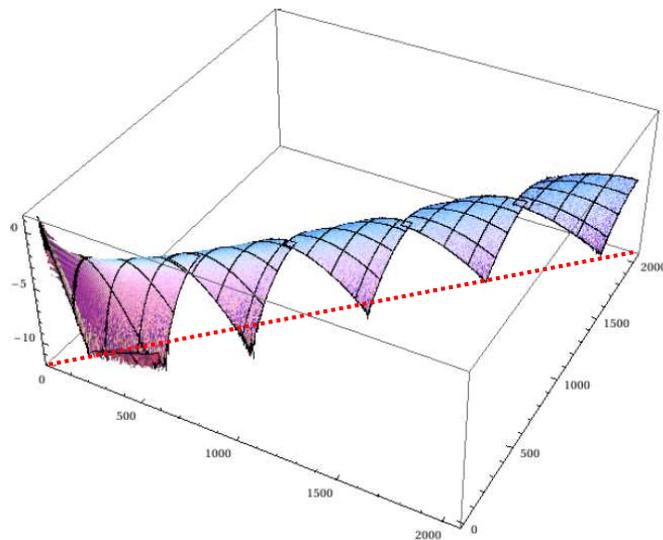

The effective action  
 Kinetic term  
**Potential term**  
 Parameters of the action

- ... and the potential term can be analyzed in detail

$$\langle n | M | m \rangle = N e^{-\frac{1}{\Gamma} \left[ \frac{(n-m)^2}{n+m-2n_0} + \mu \left( \frac{n+m}{2} \right)^{1/3} - \lambda \left( \frac{n+m}{2} \right) \right]}$$

□ For  $n=m$ :

$$\log \langle n | M | n \rangle = -\frac{1}{\Gamma} (\mu n^{1/3} - \lambda n) + \alpha$$

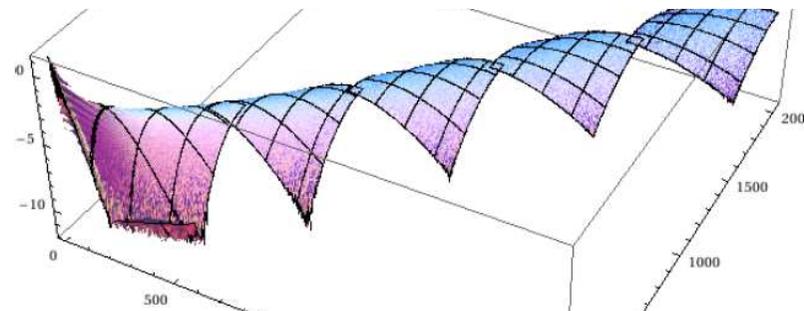

CDT basics  
 Motivation  
 The transfer matrix idea  
**Transfer matrix for large volumes**  
 Transfer matrix for small volumes

The effective action  
 Kinetic term  
 Potential term  
**Parameters of the action**

- The fits agree with the previous method based on the covariance matrix

$$\langle n | M | m \rangle = N e^{-\frac{1}{\Gamma} \left[ \frac{(n-m)^2}{n+m-2n_0} + \mu \left( \frac{n+m}{2} \right)^{1/3} - \lambda \left( \frac{n+m}{2} \right) \right]}$$

Method	$\Gamma$	$n_0$	$\mu$	$\lambda$
Cross-diagonals	$26.07 \pm 0.02$	$-3 \pm 1$	—	—
Diagonal	(26.07)	—	$16.5 \pm 0.2$	$0.049 \pm 0.001$
Full fit	$26.17 \pm 0.01$	$7 \pm 1$	$15.0 \pm 0.1$	$0.046 \pm 0.001$
Previous method*	$23 \pm 1$	—	$13.9 \pm 0.7$	$0.027 \pm 0.003$

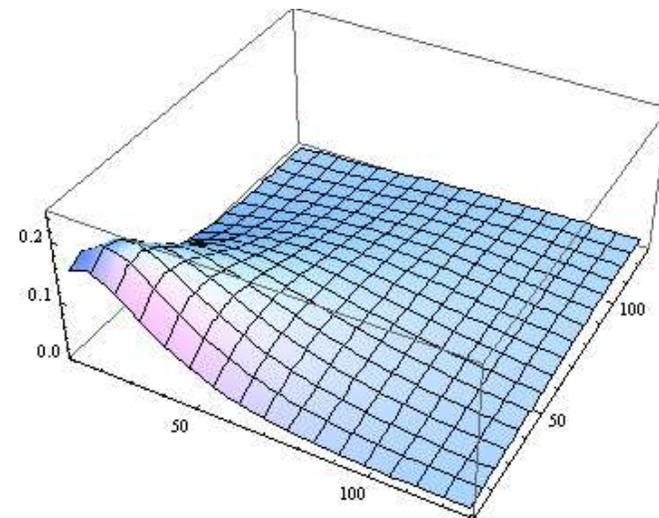

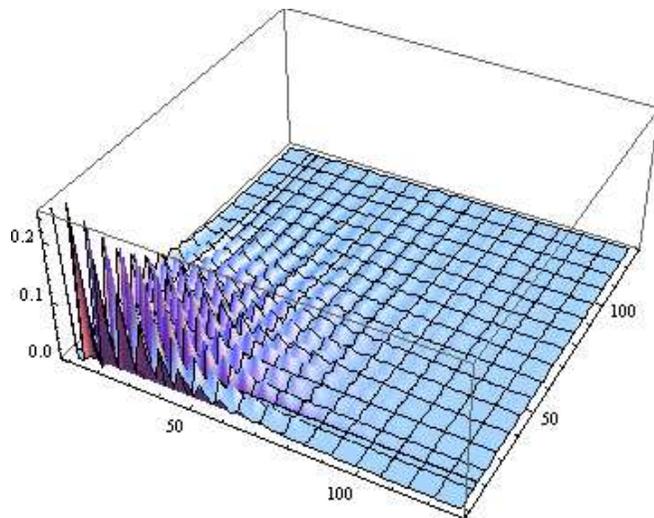

CDT basics  
Motivation  
The transfer matrix idea  
Transfer matrix for large volumes  
**Transfer matrix for small volumes**

- The transfer matrix gives access to the effective action in the ‘stalk’ range

$$\langle n | M | m \rangle = N e^{-L_{\text{eff}}(n,m)}$$

- Discretization effects (split into three families of states) makes analytical modeling difficult

- If we average over these three families  $M$  becomes smooth

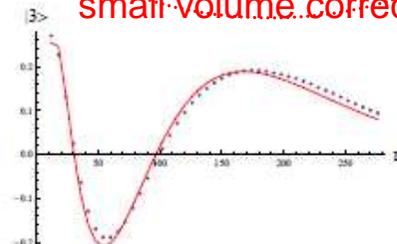

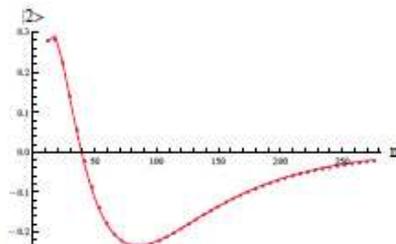

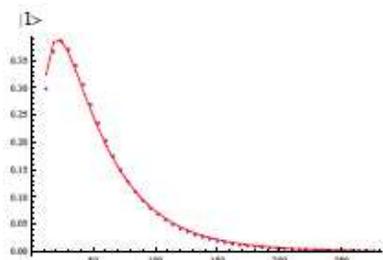

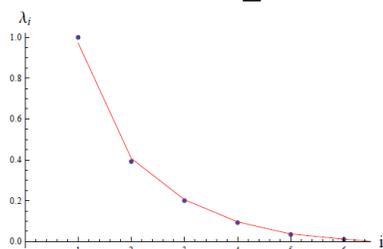

**CDT basics**  
**Motivation**  
**The transfer matrix idea**  
**Transfer matrix for large volumes**  
**Transfer matrix for small volumes**

- The effective action for the stalk is basically the same as for the 'blob'

$$S_{eff}^{stalk} = \sum_t \frac{1}{\Gamma} \left[ \frac{(n_t - n_{t+1})^2}{n_t + n_{t+1} - 2n_0} + \mu \left( \frac{n_t + n_{t+1}}{2} \right)^{1/3} - \lambda \left( \frac{n_t + n_{t+1}}{2} \right)^{1/3} + \delta \left( \frac{n_t + n_{t+1}}{2} \right)^{-\rho} \right]$$

small-volume correction

Parameter	Stalk	Blob
$\Gamma$	$27.2 \pm 0.1$	$25.7 - 26.2$
$n_0$	$5 \pm 1$	$-3 - +7$
$\mu$	$34 \pm 2$	$13 - 30$
$\lambda$	$0.12 \pm 0.02$	$0.04 - 0.07$
$\delta$	$(4 \pm 7) \times 10^4$	—
$\rho$	$3 \pm 1$	—

## Conclusions

- The transfer matrix model allows to measure the effective action directly
- The effective action in phase 'C' of CDT is very well described by the minisuperspace model
- Despite the nature of the stalk seems quite different from the blob on the first sight it is well explained by the same effective action when discretization effects are „cleared”
- We observe some correction of the potential term in the small volume range, however it is small and cannot be determined with high precision (it may be as well the effect of discretization artifacts)
- Our new method of measurement based on the transfer matrix model has a lot of advantages:
  - the effective action is measured directly  $\Rightarrow$  higher precision of the fits
  - the method is much faster (small systems  $\Rightarrow$  fast thermalization) and allows high statistics of the measurements
