Systems and

- Quantum chaos: The study of quantum systems which exhibit chaos in the classical regime.
- The level spacing distribution is an indicator of quantum chaos. Random Matrix Theory (RMT) proves to be very useful in this regard.
- The presence of regular and chaotic regions in the classical phase space of a system affects the spectral statistics of its quantum version.
- Some of these systems exhibit semiclassical phenomena like localization of states.

Systems and

- Anomalous enhancement of eigenfunction intensity.
- Can we obtain any information about the localized states by investigating the corresponding eigenvalue statistics?
- We construct a random matrix model to simulate the coupling between a localized state and its nearest neighbours.
- In this work, localized states are identified by calculating the information entropy for each eigenstate, given by:

$$S_n^\alpha = \sum_{j=1}^M |a_{n,j}^\alpha|^2 \log |a_{n,j}^\alpha|^2$$

Systems and

- Hamiltonians having time-reversal symmetry are modeled using the Gaussian Orthogonal Ensemble (GOE) class of random matrices.
- The nearest neighbour spacing distribution (NNSD) for GOE systems is given by the Wigner distribution:

$$P_W(S) = \frac{\pi}{2} S e^{-\frac{\pi}{4} S^2}$$

- Here  $S_i = E_{i+1} - E_i$ . Instead, we may also look at the ratio of spacings  $r_i = S_i/S_{i-1}$ . For the GOE case, the NNSD would then be<sup>1</sup>:

$$P_W(r) = \frac{27}{8} \frac{(r + r^2)}{(1 + r + r^2)^{5/2}}$$

Systems and

- We consider a  $3 \times 3$  real, symmetric matrix of the following type:

$$H = \begin{bmatrix} H_{11} & H_{12} & H_{13} \\ H_{12} & H_{22} & H_{23} \\ H_{13} & H_{23} & H_{33} \end{bmatrix}$$

- Here,  $\langle H_{ij} \rangle = 0$ ,  $\langle H_{ii}^2 \rangle = 1$  for  $i, j=1,2,3$ ,  
 $\langle H_{12}^2 \rangle = \frac{1}{2}$ ,  $\langle H_{13}^2 \rangle = \langle H_{23}^2 \rangle = \frac{k^2}{2}$  with  $0 \leq k \leq 1$
- We consider  $H_{33}$  to be an eigenvalue corresponding to a localized state, which is coupled to its nearest neighbours (the  $2 \times 2$  block) via the coupling parameter of strength  $k$ .

- Obtaining the eigenvalues for a closed quantum billiard system involves solving the Helmholtz equation with Dirichlet boundary conditions. That is,

$$\left[ \vec{\nabla}^2 + k^2 \right] \vec{E} = 0$$

- The chaos parameter in this problem is the shape of the billiard, varying which, the transition from integrability to chaos can be observed.
- Localized states called scars first studied in this context<sup>3</sup>.
- Depending on shape, different kinds of localized states observed, including whispering gallery modes, bouncing ball modes, bowtie modes etc.

Systems and

- Here, we consider a coupled quartic oscillator system which is classically chaotic for different values of the coupling parameter  $\alpha$ .
- The Hamiltonian for this system is given by

$$H = \frac{p_x^2}{2} + \frac{p_y^2}{2} + x^4 + y^4 + \alpha x^2 y^2$$

- The classical phase space has both regular and chaotic regions. Regular periodic orbits exist even as  $\alpha \rightarrow \infty$ .
- Quantum system exhibits localization along channel periodic orbits.

# Results

Figure : Distribution of the ratio of spacings between a localized state and its nearest neighbours for three values of  $\alpha$  for the quartic oscillator shown along with the numerical results obtained from the  $3 \times 3$  model with the appropriate value of parameter  $k$ .

- Consider real symmetric (for  $\beta = 1$ ) or Hermitian (for  $\beta = 2$ ) matrices  $H$  from the probability measure

$$\mathcal{P}(H)d[H] \propto \exp\left(-\frac{\beta}{2} \text{tr} \Sigma^{-2} H^2\right) d[H].$$

- For  $\beta=1$ , the joint probability density of eigenvalue follows as

$$P(k; \lambda_1, \lambda_2, \lambda_3) \propto |\Delta(\{\lambda\})| \int_{\mathcal{O}_3} d\mu(O) \exp\left(-\frac{1}{2} \Sigma^{-2} O \Lambda^2 O^T\right)$$

where the integral is over the group of  $3 \times 3$  orthogonal matrices with  $d\mu(O)$  representing the corresponding Haar measure.

Systems and

- A random matrix model for the coupling between a localized state and its nearest neighbours was put forth for GOE and GUE systems.
- The distribution of the ratios of level spacings (corresponding to localized states) was evaluated for some well-known quantum systems.
- This was compared with data obtained numerically (for GOE) and analytically (for GUE) for different values of the parameter, to find an appropriate fit.
- This parameter  $k$  can be considered a numerical measure of the strength of the coupling.
