

SOFT THEOREMS FOR SIGMA MODELS WITH 2D-3D TARGET SPACE

M. Shifman

William I. Fine Theoretical Physics Institute, University of Minnesota

Karol Kampf, Jiri Novotny, Jaroslav Trnka +MS

64. Cracow School of Theoretical Physics, Zakopane, Tatra Mountains, Poland; , June 15-23, 2024// JUNE 18

Soft theorems: Connecting soft limits of scattering amplitudes and sigma models

History: Gell-Mann – Levy (1960) \longleftrightarrow Adler (1965)

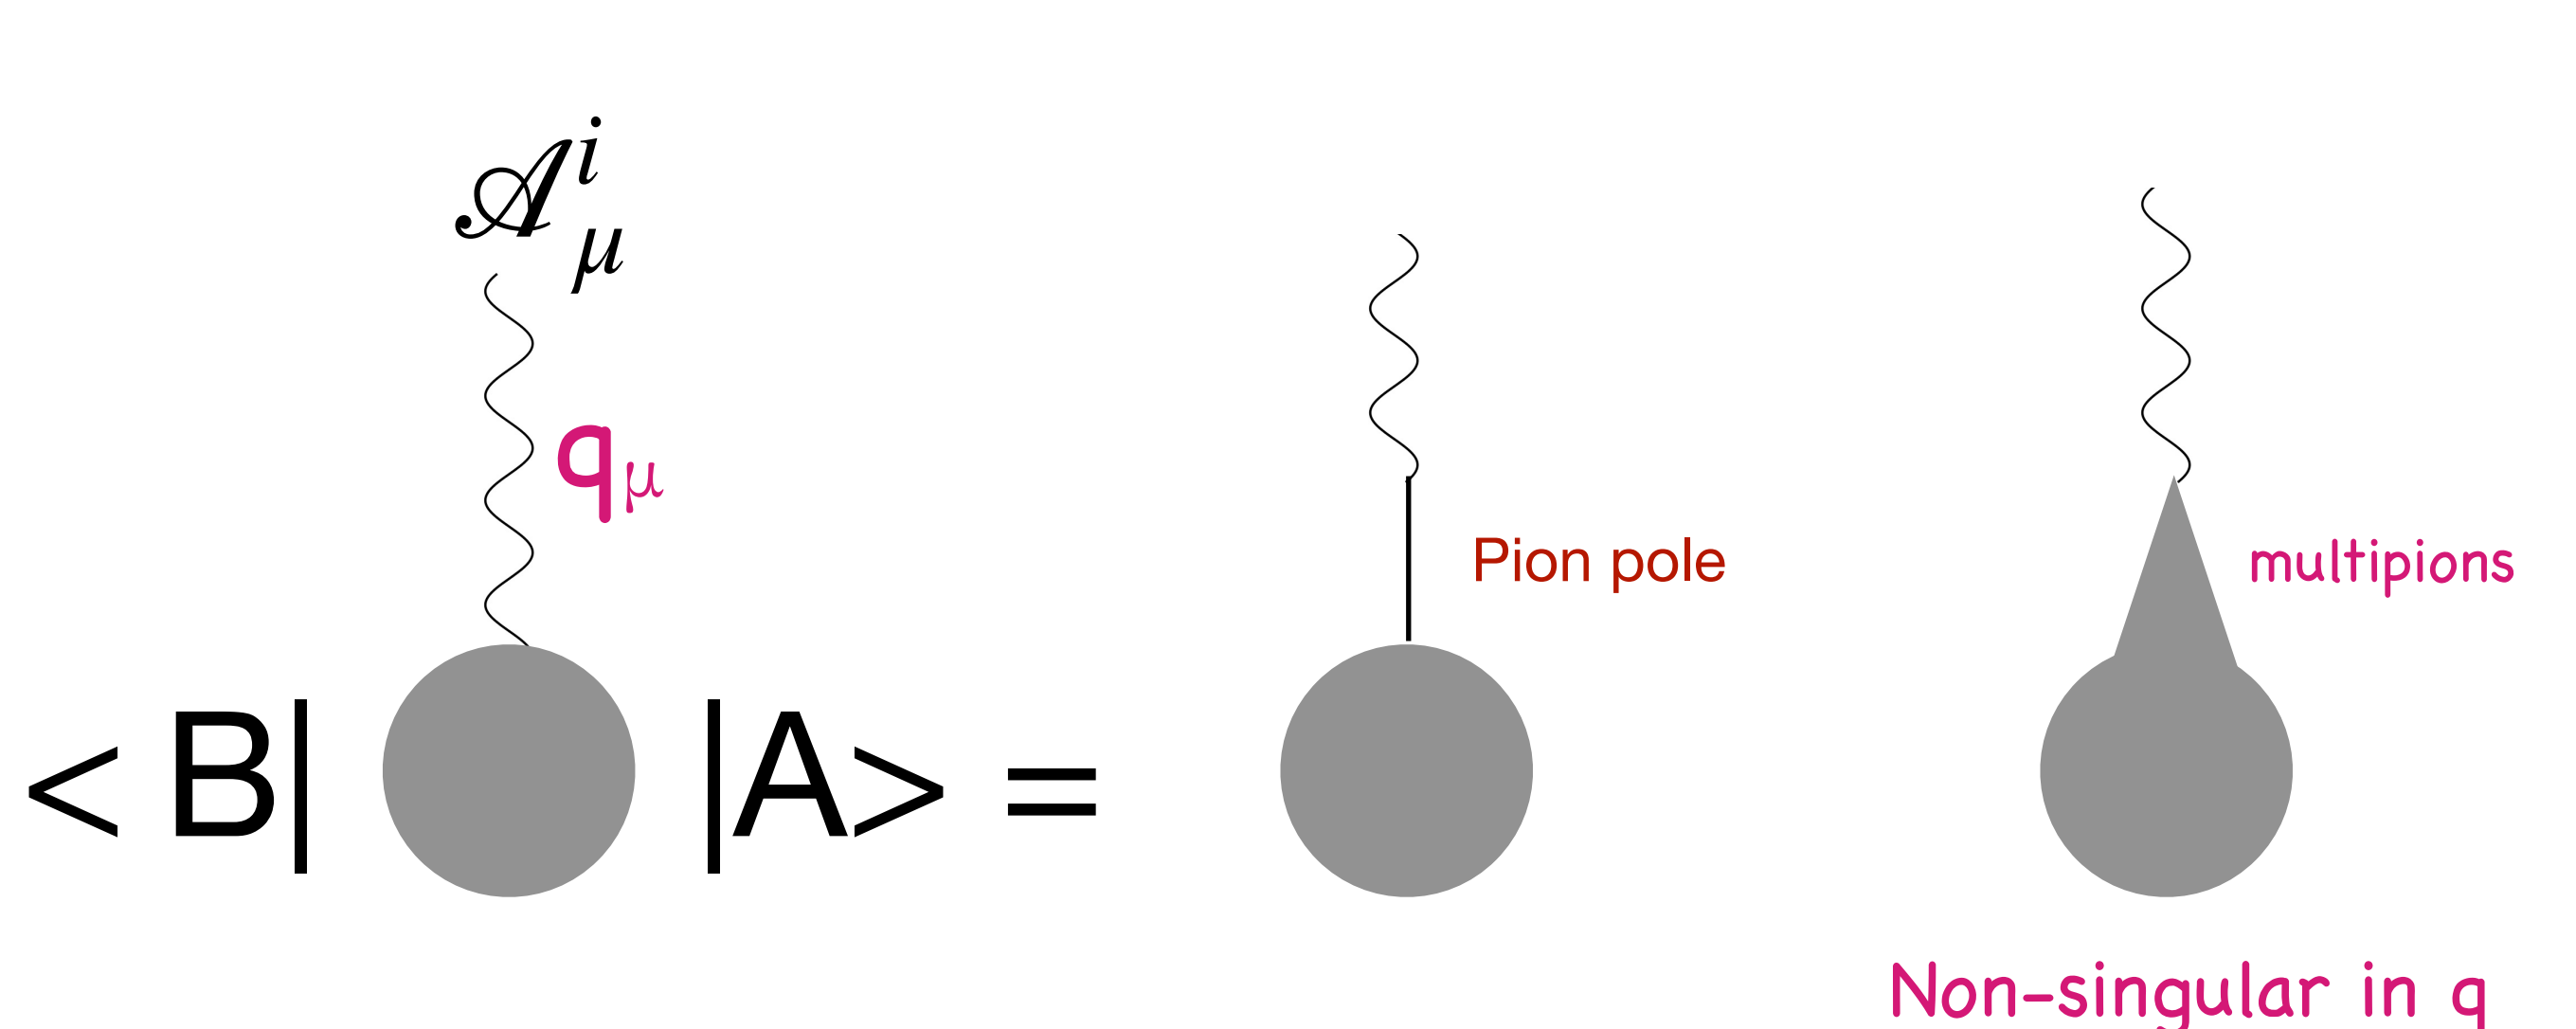

👉 The simplest case: spontaneous symmetry breaking $G \rightarrow H$, sigma model for Goldstones has coset target space G/H

Currents generating spontaneously broken symmetries are coupled to Goldstones, but are conserved

Example : (GML), SU(2) chiral symmetry in «QCD» \longleftarrow SU(2) \times SU(2)/SU(2); Three axial currents are coupled to pions

and conserved as operators $\partial^\mu \mathcal{A}_\mu^i = 0$

Adler consistency condition // Adler zero

Absence of cubic vertices CRUCIAL!

For pole

$$M(q) \rightarrow \langle \pi B | A \rangle \times (2\pi)^4 \delta^4(p_B + q - P_A) \times \frac{q_\mu}{q^2}$$

Multiply by q_μ and tend $q \rightarrow 0$

We then get $\langle \pi B | A \rangle = 0$ at $q \rightarrow 0$

Adler zero, hurrah !!!

Drastic changes the last decade or so

👉 1. How to establish soft theorems if your target space is NOT a coset? (I.e. massless scalar particles are not necessarily Goldstones!)

👉 2. Can one incorporate symmetries of sigma models directly into S-matrix?

👉 3. Some sigma models can be understood as consequence of a “generalized Adler zero” emerging in “exceptional” sigma models (whose leading interactions are uniquely fixed by a single coupling constant), namely, nonlinear sigma models, of the type CP(1), the Dirac-Born-Infeld (DBI) theory, and the so-called special Galileon.

• Cheung, K. Kampf, J. Novotny and J. Trnka (2015)

Generalized Adler zero: $M(q) = O(q^\sigma)$,

$$\mathcal{L} = (\partial\phi)^2 \sum_m \lambda_{mn} \partial^m \phi^n$$

Indices: $\sigma, m, \rho = m/n$

Dirac-Born-Infeld action: $\mathcal{L} = -b^2 \sqrt{-\det\left(\eta + \frac{F}{b}\right)} + b^2$

η is the [Minkowski metric](#), F is the [Faraday tensor](#)

Galileon is a scalar field whose action is invariant under Galilean transformations, e.g.

$$\text{Gal}_3^1 \rightarrow \partial_\mu \pi \partial^\mu \pi (\partial^2) \pi - \partial_\mu \pi \partial^\mu \partial^\nu \pi \partial_\nu \pi$$

Variety of Soft Recursion Relations: What particular sigma models will be considered?

Model 1: U(1) fibration of CP(1)~O(3):

3D target space

Model 2: U(1) Lie-algebraic generalization of CP(1)~O(3):

2D target space

$$\mathbf{S}_i \mathbf{S}_i = 1$$

unit (iso)vector

Nearest-neighbors isotropic interaction

$$\mathcal{H} \rightarrow \mathcal{L}_{\text{Euclid}} = \frac{1}{2g^2} \partial_\mu \mathbf{S} \partial_\mu \mathbf{S} \rightarrow G \partial_\mu \phi^\dagger \partial_\mu \phi = \frac{1}{2g^2} \frac{1}{(1 + \phi^\dagger \phi)^2} \partial_\mu \phi^\dagger \partial_\mu \phi$$

2D

3D

2D

Adler Zeroes: if $T = \text{coset } G/H$, e.g. $CP(1)$ or PCM. (Modulo some nuances)
Spontaneously broken currents are crucial!

If not ALL massless particles are Goldstone ($T \neq \text{coset}$), then
Adler zeros \rightarrow Recursions

Typically,

$p = p_1 + p_2 \rightarrow$ pole singularity

To avoid Adler zero and arrive at recursions, generically, both even- and odd-particle amplitudes $\neq 0$. Some other necessary conditions apply, e.g. linear terms in nonlinearly realized sim transformations

Cheung review + Cheung, K. Kampf, J. Novotny and J. Trnka (2015)

Noncollinear magnetic phenomena in correlated electron systems in cont. limit are described by a sigma model on target space with a geometry that **interpolates** between **2D** sphere S_2 and **3D** sphere S_3

Gell-Mann–Levy representation for three pions

$$\mathcal{H} = \frac{1}{2g^2} \int dx \left\{ \left[\sum_{a=1,2,3} J_\mu^a J_\mu^a \right] - \kappa J_\mu^3 J_\mu^3 \right\},$$

$$U(x) \in SU(2)$$

$$0 \leq \kappa \leq 1$$

$$J_\mu = -iU^\dagger \partial_\mu U \equiv \sum_a 2 J_\mu^a T^a, \quad J_\mu^a = \text{Tr} \left(J_\mu T^a \right), \quad U^\dagger U = 1$$

If $\kappa = 1$, then CP^1 model

Target = 2D sphere

Coset $SU(2)/U(1)$ and $sl(2)$

If $\kappa = 0$, then $U(1)$ Principal Chiral Model GML

Target = 3D sphere

Coset $SU(2) \times SU(2)/SU(2)$

If $0 < \kappa < 1$, then $U(1)$ fibration over CP^1

Adler Zeroes \rightarrow Soft Recursion Relations

$$[SU(N)/(SU(N-1) \times U(1))] \times U(1) \sim SU(N)/SU(N-1) \longrightarrow \dim = 2N-1$$

For generic k cubic vertices are present

$$\mathcal{L} = \frac{1}{2} \partial_\mu \phi_I \partial^\mu \phi_I + \frac{1}{2} K_{IJK} \partial_\mu \phi_I \partial^\mu \phi_J \phi_K + \mathcal{O}(\phi^4)$$

$$N_\mu^J = \sum_{I=1}^N F_I^J \partial_\mu \phi_I + \sum_{L,K=1}^N \kappa_{LK}^J \phi_K \partial_\mu \phi_L + \mathcal{O}(\phi^3)$$

$$\lim_{p \rightarrow 0} \sum_{I=1}^N F_I^J A_n(\alpha + \phi_I(p), \beta) = \sum_{I \in \alpha \cup \beta} \sum_{K=1}^N c_{IK}^J A_{n-1}^{K,I}(\alpha, \beta).$$

In the soft limit $p \rightarrow 0$ n -leg amplitude through a sum of $(n-1)$ amplitudes 🙌

$[SU(2)/U(1)] \times U(1)$

SU(2) Example (Soft Recursion Relations)

3 massless ϕ^+, ϕ^-, χ

Verify 5-leg ampl vs. sum of 4-leg ampl

GENERAL $[SU(N)/(SU(N-1) \times U(1))] \times U(1)$

$[SU(2)/U(1)] \times U(1)$

$$A_4(\phi_1^+, \phi_2^+, \phi_3^-, \phi_4^-) = \frac{1}{4F^4} (3F_0^2 - 8F^2) s_{12},$$

$$A_4(\phi_1^+, \phi_2^-, \chi_3, \chi_4) = \frac{F_0^2}{4F^4} s_{12},$$

$$A_5(\phi_1^+, \phi_2^+, \phi_3^-, \phi_4^-, \chi_5) = \frac{iF_0}{F^6} \left(F^2 - \frac{F_0^2}{2} \right) (s_{12} - s_{34}).$$

The soft theorem for $p_1 \rightarrow 0$ predicts,

$$\begin{aligned} \lim_{p_1 \rightarrow 0} A_5 &= \frac{iF_0}{2F^2} A_4(\phi_5^+, \phi_2^+, \phi_3^-, \phi_4^-) \\ &\quad - \frac{iF_0}{2F^2} [A_4(\phi_2^+, \phi_3^-, \chi_4, \chi_5) + A_4(\phi_2^+, \phi_4^-, \chi_3, \chi_5)] \\ &= -\frac{iF_0}{F^6} \left(F^2 - \frac{F_0^2}{2} \right) s_{34}, \end{aligned}$$

$$F_0 = \frac{1}{g} \sqrt{1 - \kappa}, \quad F = \frac{1}{\sqrt{2}g}, \quad s_{ij} = (p_i + p_j)^2$$

Praszałowicz-Fest

Michał was instrumental in many developments in the Skyrme theory which were mentioned in Larry McLerran presentation

A few remarks after Larry McLerran: today's advances in Skyrmsions and related theories

From page 6:

$$\mathcal{H} = \frac{1}{2g^2} \int dx \left\{ \left[\sum_{a=1,2,3} J_\mu^a J_\mu^a \right] - \kappa J_\mu^3 J_\mu^3 \right\},$$

$\kappa = 1 \rightarrow \mathbb{C}P^1$; $\kappa = 0 \rightarrow \text{PCM} \rightarrow \text{Skyrme model}$

↓
Faddeev-Niemi Hopfions

↑
U(1) fibration over $\mathbb{C}P^{N-1}$

Limit $\kappa \sim 1$ reduces to a frustrated magnetic system earlier considered by Sutcliffe as a host to Hopfions;

Limit $\kappa \sim 0$ is similar to the 3D Skyrme model.

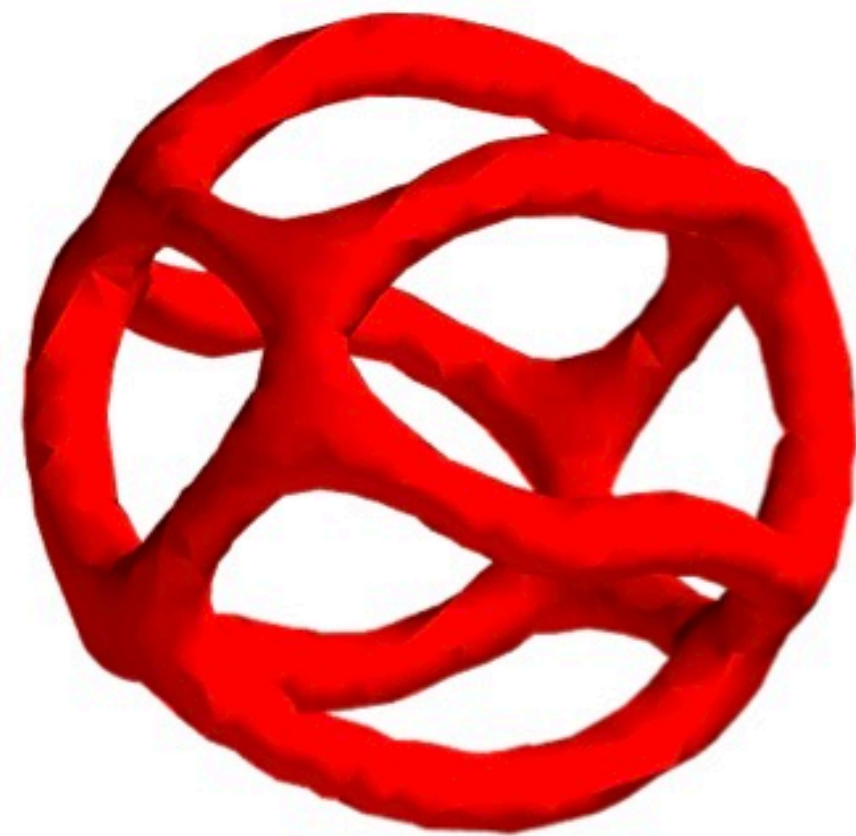

(a) $\mathcal{K} = 0$

(b) $\mathcal{K} = 0.5$

(c) $\mathcal{K} = 0.77$

$Q=7$

Skyrmion

Hopfion

(a) Position curve of a $Q=7$ Skyrminion at $\kappa = 0$; (b) For positive relatively small κ this settles to a three loop configuration; The three-loop solution may be tracked for increasing κ , but it develops an instability at $\kappa = 0.77$ and settles to a distinct buckled loop configuration

Conclusions

Dynamics of Goldstone massless particles for target spaces of $SU(N)/SU(N-1)$ i.e. $U(1)$ fibrations of CP^{N-1} :

Special Recursions. Lagrangian can be uniquely fixed if we start from these recursions.

Skymion and Hopfion topological numbers are related; There is a continuous path in κ leading from one to another
