The Royal Swedish Academy of Sciences has decided to award the Nobel Prize in Physics for 2013 to

François Englert and Peter Higgs

“for the theoretical discovery of a mechanism that contributes to our understanding of the origin of mass of subatomic particles, and which recently was confirmed through the discovery of the predicted fundamental particle, by the ATLAS and CMS experiments at CERN’s Large Hadron Collider”

8 October 2013

The Royal Swedish Academy of Sciences has decided to award the Nobel Prize in Physics for 2013 to

François Englert and Peter Higgs

“for the theoretical discovery of a mechanism that contributes to our understanding of the origin of mass of subatomic particles, and which recently was confirmed through the discovery of the predicted fundamental particle, by the ATLAS and CMS experiments at CERN’s Large Hadron Collider”

Not the origin of Mass

- Gallilean and Newtonian concept of mass :

Inertial mass ($F=ma$)

Gravitational mass ($P=mg$)

Single concept: conserved intrinsic property of matter where the total mass of a system is the sum of its constituents

- Einstein : Does the mass of a system depend of its energy content?

Mass = rest energy of a system or $m_0=E/c^2$

- Atomic level : binding energy $\sim O(10\text{eV})$ which is $\sim 10^{-8}$ of the mass

- Nuclear level (nucleons) : binding energy $\sim 2\%$ of the mass

- **Nucleon level (partons) : binding energy $\sim 98\%$ of the mass**

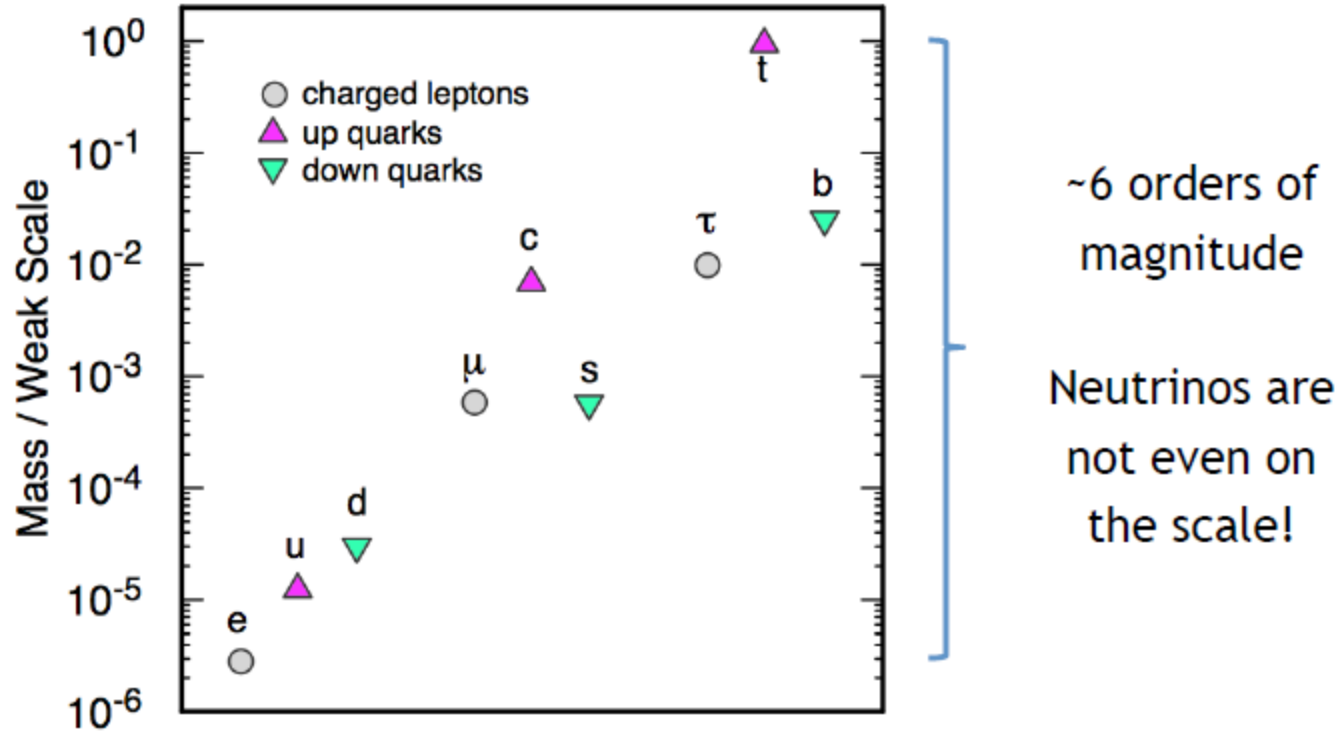

Most of the (luminous) mass in the universe comes from QCD confinement energy

The insight(s) of the BEH mechanism :

Making the weak force weak (short range, or W and Z bosons massive)
and allowing fermion masses in the theory

Not explaining the flavor Hierarchy

Replacing mass terms by Yukawa couplings

The BEH sector includes most of the free parameters of the Standard Model

How Would it Be Without Elementary Particle Masses?

Electron mass ($m_e = 511 \text{ keV}$)

Bohr Radius $a = 1/(a_{EM} m_e)$ so :

If $m_e = 0$: Then no atomic binding

W boson mass ($m_W = 81 \text{ GeV}$)

$$G_F \sim (M_W)^{-2}$$

If no or lower W mass : shorter
combustion time at lower temperature

Everything would be completely
different!

Preamble

Historical context and roots of the Standard Model and Higgs Mechanism

1864-1958 - Abelian theory of quantum electrodynamics

1933-1960 - Fermi model of weak interactions

1954 - Yang-Mills theories for gauge interactions...

1957-59 – Schwinger, Bludman and Glashow introduce W bosons for the weak charged currents...

...birth of the idea of unified picture for the electromagnetic and weak interaction in ...

$$SU(2)_L \times U(1)_Y$$

Caution, not unified in the sense of unified forces, only unique framework

... but local gauge symmetry forbids gauge bosons and fermion masses.

How Does Mass Appear in a Lagrangian

$$m\bar{\psi}\psi$$

In Terms of Feynman Diagram

1960

Spontaneous Symmetry Breaking (SSB) - Global Symmetry

The Goldstone theorem is where it all began...

Massless scalars occur in a theory with SSB (or more accurately where the continuous symmetry is not apparent in the ground state).

Originates from the work of Landau (1937)

From a simple (complex) scalar theory with a U(1) symmetry

$$\varphi = \frac{\phi_1 + i\phi_2}{\sqrt{2}} \quad L = \partial_\nu \varphi^* \partial^\nu \varphi - V(\varphi) \quad V(\varphi) = \mu^2 \varphi^* \varphi + \lambda(\varphi^* \varphi)^2$$

The Lagrangian is invariant under : $\varphi \rightarrow e^{i\alpha} \varphi$

Shape of the potential if $\mu^2 < 0$ and $\lambda > 0$ necessary for SSB and be bounded from below.

Change frame to local minimum frame :

$$\varphi = \frac{v + \eta + i\xi}{\sqrt{2}} \quad \text{No loss in generality.}$$
$$L = \frac{1}{2} \underbrace{\partial_\nu \xi \partial^\nu \xi}_{\text{Massless scalar}} + \frac{1}{2} \underbrace{\partial_\nu \eta \partial^\nu \eta + \mu^2 \eta^2}_{\text{Massive scalar}} + \text{interaction terms}$$

Massless scalar

Massive scalar

Nice but what should we do with these massless scalars?

1964 -The Higgs mechanism : How gauge bosons can acquire a mass.

Spontaneous Symmetry Breaking (SSB) Extended to **Local Symmetry**

Let the aforementioned continuous symmetry U(1) be local : $\alpha(x)$ now depends on the space-time x .

$$\varphi \rightarrow e^{i\alpha(x)}\varphi$$

The Lagrangian can now be written : $L = (D_\nu \varphi)^* D^\nu \varphi - V(\varphi) - \frac{1}{4} F_{\mu\nu} F^{\mu\nu}$

In terms of the covariant derivative : $D_\nu = \partial_\nu - ieA_\nu$

The gauge invariant field strength tensor : $F^{\mu\nu} = \partial^\mu A^\nu - \partial^\nu A^\mu$

And the Higgs potential : $V(\varphi) = \mu^2 \varphi^* \varphi + \lambda(\varphi^* \varphi)^2$

Here the gauge field transforms as : $A_\mu \rightarrow A_\mu + \frac{1}{e} \partial_\mu \alpha$

Again translate to local minimum frame : $\varphi = \frac{v + \eta + i\xi}{\sqrt{2}}$

$$L = \frac{1}{2} \partial_\nu \xi \partial^\nu \xi + \frac{1}{2} \partial_\nu \eta \partial^\nu \eta + \mu^2 \eta^2 - v^2 \lambda \eta^2 + \frac{1}{2} \underbrace{e^2 v^2 A_\mu A^\mu}_{\text{Mass term}} - ev A_\mu \partial^\mu \xi - F^{\mu\nu} F_{\mu\nu} + \text{ITs}$$

Mass term for the gauge field! But...

What about the field content?

A massless Goldstone boson ξ , a massive scalar η and a massive gauge boson!

Number of d.o.f. : 1 1 1

Number of initial d.o.f. : 2 **Oooops... Problem!**

But wait! Halzen & Martin p. 326

The term $evA_\mu\partial^\mu\xi$ is unphysical

The Lagrangian should be re-written using a more appropriate expression of the translated scalar field choosing a particular gauge where $h(x)$ is real :

$$\varphi = (v + h(x))e^{i\frac{\theta(x)}{v}}$$

Then the gauge transformations are : $\varphi \rightarrow e^{-i\frac{\theta(x)}{v}}\varphi$ $A_\mu \rightarrow A_\mu + \frac{1}{ev}\partial_\mu\theta$

$$L = \frac{1}{2}\partial_\nu h\partial^\nu h - \lambda v^2 h^2 - \lambda v h^3 - \frac{1}{4}\lambda h^4$$

Massive scalar : The Higgs boson

$$+(1/2)e^2 v^2 A_\mu A^\mu - F^{\mu\nu} F_{\mu\nu}$$

Massive gauge boson

$$+(1/2)e^2 A_\mu A^\mu h^2 + ve^2 A_\mu A^\mu h$$

Gauge-Higgs interaction

The Goldstone boson does not appear anymore in the Lagrangian

1968

A MODEL OF LEPTONS*

Steven Weinberg†

Laboratory for Nuclear Science and Physics Department,
Massachusetts Institute of Technology, Cambridge, Massachusetts

(Received 17 October 1967)

Leptons interact only with photons, and with the intermediate bosons that presumably mediate weak interactions. What could be more natural than to unite¹ these spin-one bosons into a multiplet of gauge fields? Standing in the way of this synthesis are the obvious differences in the masses of the photon and intermediate meson, and in their couplings. We might hope to understand these differences by imagining that the symmetries relating the weak and electromagnetic interactions are exact symmetries of the Lagrangian but are broken by the vacuum. However, this raises the specter of unwanted massless Goldstone bosons.² This note will describe a model in which the symmetry between the electromagnetic and weak interactions is spontaneously broken, but in which the Goldstone bosons are avoided by introducing the photon and the intermediate-boson fields as gauge fields.³ The model may be renormalizable.

We will restrict our attention to symmetry groups that connect the observed electron-type leptons only with each other, i.e., not with muon-type leptons or other unobserved leptons or hadrons. The symmetries then act on a left-handed doublet

$$L = \left[\frac{1}{2}(1 + \gamma_5) \right] \begin{pmatrix} \nu_e \\ e \end{pmatrix} \quad (1)$$

and on a right-handed singlet

$$R = \left[\frac{1}{2}(1 - \gamma_5) \right] e. \quad (2)$$

The large

ian cons
on L , pl
right-ha
as we kn
tially un
and the
gauge fi
metry w
massless
form ou
spin \bar{T} a
+ $\frac{1}{2}N_L$.

Is this model renormalizable? We usually do not expect non-Abelian gauge theories to be renormalizable if the vector-meson mass is not zero, but our Z_μ and W_μ mesons get their mass from the spontaneous breaking of the symmetry, not from a mass term put in at the beginning. Indeed, the model Lagrangian we start from is probably renormalizable

Therefore, we shall construct our Lagrangian out of L and R , plus gauge fields \bar{A}_μ and B_μ cou
blet

Of course our model has too many arbitrary features for these predictions to be taken very seriously

whose
and Y and give the electron its mass. The only renormalizable Lagrangian which is invariant under \bar{T} and Y gauge transformations is

Milestone PRL 1967

Assuming a third weak gauge boson the initial number of **gauge boson d.o.f. is 8**, to give mass to three gauge bosons at least one doublet of scalar fields is necessary (**4 d.o.f.**) :

$$\phi = \frac{1}{\sqrt{2}} \begin{pmatrix} \phi^+ \\ \phi^0 \end{pmatrix}$$

Setting aside the gauge kinematic terms the Lagrangian can be written :

$$\mathcal{L} = (D_\mu \phi)^\dagger (D^\mu \phi) - V(\phi) \quad \left\{ \begin{array}{l} D_\mu = \partial_\mu - ig\vec{W}_\mu \cdot \vec{\sigma} - ig' \frac{Y}{2} B_\mu \\ V(\phi) = \mu^2 \phi^\dagger \phi + \lambda (\phi^\dagger \phi)^2 \end{array} \right.$$

The next step is to develop the Lagrangian near : $\langle \phi \rangle = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ v \end{pmatrix}$

Choosing the specific real direction of charge 0 of the doublet is not fortuitous :

$$\phi = e^{-i\vec{\sigma} \cdot \vec{\xi}} \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ H + v \end{pmatrix} \quad \text{In particular for a non charged vacuum}$$

Again choosing the gauge that will absorb the Goldstone bosons $\xi \dots$

Then developing the covariant derivative for the Higgs field :

Just replacing the Pauli matrices :

$$D_\mu \varphi = \partial_\mu \varphi - \frac{i}{2} \begin{pmatrix} gW_\mu^3 + g'B_\mu & g(W_\mu^1 - iW_\mu^2) \\ g(W_\mu^1 + iW_\mu^2) & -gW_\mu^3 + g'B_\mu \end{pmatrix} \varphi$$

Then using : $W_\mu^\pm = \frac{W_\mu^1 \mp iW_\mu^2}{\sqrt{2}}$

$$D_\mu \varphi = \partial_\mu \varphi - \frac{i}{2} \begin{pmatrix} gW_\mu^3 + g'B_\mu & \sqrt{2}gW_\mu^+ \\ \sqrt{2}gW_\mu^- & -gW_\mu^3 + g'B_\mu \end{pmatrix} \varphi = \begin{pmatrix} 0 \\ \partial_\mu h \end{pmatrix} - \frac{i}{2} \begin{pmatrix} \sqrt{2}gvW_\mu^+ + \sqrt{2}ghW_\mu^+ \\ -gvW_\mu^3 + g'vB_\mu - ghW_\mu^3 + g'hB_\mu \end{pmatrix}$$

For the mass terms only :

$$(D_\mu \varphi)^\dagger D^\mu \varphi = \partial_\mu h \partial^\mu h + \frac{1}{4} g^2 v^2 W_\mu^+ W^{-\mu} + \frac{1}{8} \begin{pmatrix} W_\mu^3 & B_\mu \end{pmatrix} \begin{pmatrix} g^2 v^2 & -gg'v^2 \\ -gg'v^2 & g'^2 v^2 \end{pmatrix} \begin{pmatrix} W^{3\mu} \\ B^\mu \end{pmatrix}$$

Explicit mixing of W^3 and B .

Finally the full Lagrangian will then be written :

$$\begin{aligned}
 \mathcal{L} = & \frac{1}{2} \partial_\mu H \partial^\mu H - \frac{1}{2} \lambda v^2 H^2 - \lambda v H^3 - \frac{\lambda}{4} H^4 && \text{Massive scalar : The Higgs boson} \\
 & + \frac{1}{2} \left[\frac{g'^2 v^2}{4} B_\mu B^\mu - \frac{gg'v^2}{2} W_\mu^3 B^\mu + \frac{g^2 v^2}{4} \vec{W}_\mu \cdot \vec{W}^\mu \right] && \text{Massive gauge bosons} \\
 & + \frac{1}{v} \left[\frac{g'^2 v^2}{4} B_\mu B^\mu H - \frac{gg'v^2}{2} W_\mu^3 B^\mu H + \frac{g^2 v^2}{4} \vec{W}_\mu \cdot \vec{W}^\mu H \right] \\
 & + \frac{1}{2v^2} \left[\frac{g'^2 v^2}{4} B_\mu B^\mu H^2 - \frac{gg'v^2}{2} W_\mu^3 B^\mu H^2 + \frac{g^2 v^2}{4} \vec{W}_\mu \cdot \vec{W}^\mu H^2 \right] && \left. \vphantom{\frac{1}{v}} \right\} \text{Gauge-Higgs interaction}
 \end{aligned}$$

In order to derive the mass eigenstates :

Diagonalize the mass matrix $\frac{1}{4} \begin{pmatrix} g^2 v^2 & -gg'v^2 \\ -gg'v^2 & g'^2 v^2 \end{pmatrix} = \mathcal{M}^{-1} \begin{pmatrix} m_Z^2 & 0 \\ 0 & 0 \end{pmatrix} \mathcal{M}$

Where

$$\mathcal{M} = \begin{pmatrix} \cos \theta_W & -\sin \theta_W \\ \sin \theta_W & \cos \theta_W \end{pmatrix} \quad \sin \theta_W = \frac{g'}{\sqrt{g^2 + g'^2}} \quad \cos \theta_W = \frac{g}{\sqrt{g^2 + g'^2}}$$

The Weinberg angle was actually first introduced by Glashow (1960)

The sector of Fermions (kinematic)

Another important consequence of the Weinberg Salam Model...

A specific $SU(2)_L \times U(1)_Y$ problem : $m\bar{\psi}\psi$ manifestly not gauge invariant

$$m\bar{\psi}\psi = m\bar{\psi}\left(\frac{1}{2}(1-\gamma^5) + \frac{1}{2}(1+\gamma^5)\right)\psi = m(\bar{\psi}_L\psi_R + \bar{\psi}_R\psi_L)$$

- neither under $SU(2)_L$ doublet and singlet terms together
- nor under $U(1)_Y$ do not have the same hypercharge

Fermion mass terms are forbidden

Not the case for Yukawa couplings to the Higgs doublet

Then after SSB one recovers :

$$\frac{\lambda_\psi v}{\sqrt{2}}\bar{\psi}\psi + \frac{\lambda_\psi}{\sqrt{2}}H\bar{\psi}\psi$$

Which is invariant under $U(1)_{EM}$

Very important : **The Higgs mechanism DOES NOT predict fermion masses**
...Yet the coupling of the Higgs to fermions is proportional to their masses

But wait...

The coupling to the Higgs fields is the following :

$$\lambda_d (\bar{u}_L, \bar{d}_L) \begin{pmatrix} 0 \\ v + h \end{pmatrix} d_R + H.C. = \lambda_d \bar{Q}_L \phi d_R$$

Can be seen as giving mass to down type fermions...

To give mass to up type fermions, need to use a slightly different coupling :

$$\phi^C = i\sigma_2 \phi^* \quad \lambda_u \bar{Q}_L \phi^C \bar{u}_R = \lambda_u (\bar{u}_L, \bar{d}_L) \begin{pmatrix} v + h \\ 0 \end{pmatrix} d_R + H.C.$$

One doublet of complex scalar fields is sufficient to accommodate mass terms for gauge bosons and fermions !

... But not necessarily only one!

$$g_{Hff} = m_f/v$$

$$g_{HVV} = 2M_V^2/v$$

$$g_{HHVV} = 2M_V^2/v^2$$

$$g_{HHH} = 3M_H^2/v$$

$$g_{HHHH} = 3M_H^2/v^2$$

Gauge-Higgs and interactions

More directly testable relations!

Prediction of the Model

Beside the existence of the Z massive neutral gauge boson...

The existence of a massive scalar :

The Higgs Particle

Whose mass (as λ) was an unknown parameter of the theory

$$v = -\frac{\mu^2}{\lambda}$$

The first very important consequences of this mechanism :

1.- Two massive charged vector bosons :

$$m_W^2 = \frac{g^2 v^2}{4}$$

Corresponding to the observed charged currents

Thus $v = 246$ GeV

Given the known W mass and g coupling

2.- One massless vector boson : $m_\gamma = 0$

The photon corresponding to the unbroken $U(1)_{EM}$

3.- One massive neutral vector boson Z :

$$m_Z^2 = (g^2 + g'^2)v^2/4$$

4.- One massive scalar particle : **The Higgs boson**

Whose mass is an unknown parameter of the theory as the quartic coupling λ

$$m_H^2 = \frac{4\lambda(v)m_W^2}{g^2}$$

Which of these consequences are actually predictions ?

- 1.- The theory was chosen in order to describe the weak interactions mediated by charged currents.
- 2.- The masslessness of the photon is a consequence of the choice of developing the Higgs field in the neutral and real part of the doublet.
- 3 & 4.- The appearance of massive Z and Higgs bosons are actually predictions of the model.

One additional very important prediction which was not explicitly stated in Weinberg's fundamental paper... although it was implicitly clear :

There is a relation between the ratio of the masses and that of the couplings of gauge bosons :

$$\frac{M_W}{M_Z} = \frac{g^2}{g^2 + g'^2} = \cos^2 \theta_W$$

or

$$\rho \equiv \frac{m_W^2}{m_Z^2 \cos^2 \theta_W} = 1$$

Absolute Lower Limit on the Higgs Mass at LEP

LEP1 e^+e^- at COM $\sim m_Z$

Various decays and topologies

Limit down to below $2m_e$ using acoplanar lepton pairs (Higgs is long lived)

LEP2 e^+e^- up to 209 GeV

(mostly $b\bar{b}$ and $\tau\tau$ decays)

Excludes SM Higgs with mass below 114 GeV

Phys.Lett. B716 (2012) 30-61

H- $\rightarrow\gamma\gamma$: events signature

Simple event signature

- Two high p_T photons
 $p_{T_1} > 40$ GeV and $p_{T_2} > 30$ GeV
- High trigger efficiency
 $\sim 99\%$
- High event selection efficiency
despite high jet-jet & γ -jet
production
 $\sim 40\%$
- High signal over background
 $\sim 3-10\%$ (depending on sub-category)

Invariant mass reconstruction $m_{\gamma\gamma}^2 = 2 * E_1 E_2 (1 - \cos \alpha)$

- Good energy calibration
- Robust primary vertex reconstruction

\rightarrow Excellent invariant mass resolution ~ 1.6 GeV with 90% of events within $\pm 2\sigma$

Shower shapes and vertex reconstr.

Photon ID 2 – Photon shower shapes and background rejection

π^0 - γ Rejection

- Photons shower shape distributions in LAr sampling layers - different for signal and background (π^0)

Vertex Reconstruction

$$m_{\gamma\gamma}^2 = 2 * E_1 E_2 (1 - \cos \alpha)$$

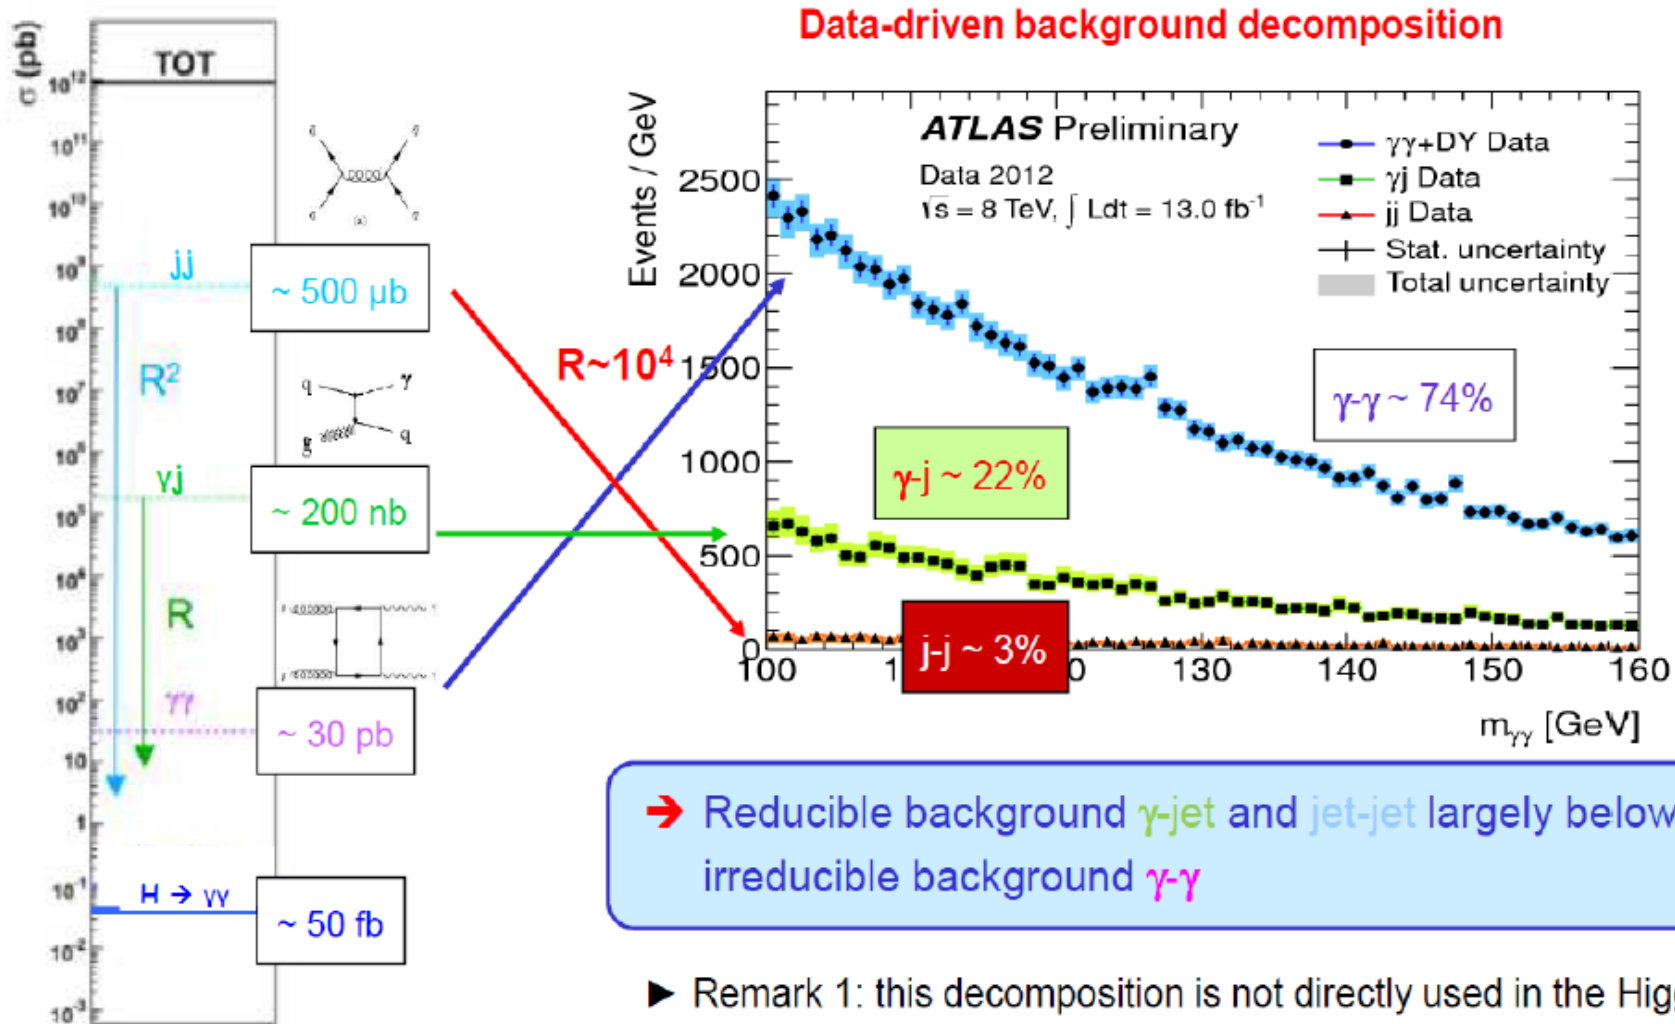

☐ Vertex reconstructed through likelihood combination

- Calorimeter 'pointing'
- Σ tracks pT^2
- Conversion vertex
- Mean vertex position

Calo pointing

H- $\rightarrow\gamma\gamma$: background rejection

➔ Reducible background $\gamma\text{-jet}$ and jet-jet largely below irreducible background $\gamma\text{-}\gamma$

- ▶ Remark 1: this decomposition is not directly used in the Higgs search: the background is extrapolated from data sidebands
- ▶ Remark 2: Drell-Yan \sim negligible for $m_{\gamma\gamma} > 100 \text{ GeV}$ ($\sim 1\%$)

The golden channel: $H \rightarrow ZZ, Z \rightarrow ll$

In a m_{4l} window
around 120-130 GeV:

	Signal	$ZZ^{(*)}$	$Z + \text{jets}, t\bar{t}$	Observed
4μ	2.09 ± 0.30	1.12 ± 0.05	0.13 ± 0.04	6
$2e2\mu/2\mu2e$	2.29 ± 0.33	0.80 ± 0.05	1.27 ± 0.19	5
$4e$	0.90 ± 0.14	0.44 ± 0.04	1.09 ± 0.20	2

Signal and background

Irreducible background

The final state is exactly the same, but it does not come from the particle you are looking for

Reducible background

The final state looks like the same, but some of the particles fake what you are looking for

4e candidate. $m_{4\ell} = 124.6$ GeV, $m_{12} = 70.6$ GeV, $m_{34} = 44.7$ GeV.

e_1 : $P_T = 24.9$ GeV, $\eta = -0.33$, $\phi = 1.98$

e_2 : $P_T = 53.9$ GeV, $\eta = -0.40$, $\phi = 1.69$

e_3 : $P_T = 61.9$ GeV, $\eta = -0.12$, $\phi = 1.45$

e_4 : $P_T = 17.8$ GeV, $\eta = -0.51$, $\phi = 2.84$

Which Higgs boson we have discovered?

Higgs boson was discovered in ZZ^* , $\gamma\gamma$ and WW^* decays

- Higgs boson mass is ~ 125.6 GeV

Measured in $H \rightarrow ZZ^* \rightarrow 4l$ and $H \rightarrow \gamma\gamma$

ATLAS: $m_H = 125.5 \pm 0.2$ (stat) ± 0.6 (syst) GeV

CMS: $m_H = 125.7 \pm 0.3$ (stat) ± 0.3 (syst) GeV

- ATLAS and CMS data strongly favour $J^P = 0^+$ SM quantum numbers; alternative models excluded at 95% CL.
- Signal strength $\mu = \sigma/\sigma_{SM}$ consistent with 1

Summer 2013:

All measured properties are compatible with SM hypothesis.

Nobel price for predicting Higgs particle

THE BEH-MECHANISM, INTERACTIONS WITH SHORT RANGE FORCES
AND SCALAR PARTICLES

8 October 2013

The Royal Swedish Academy of Sciences has decided to award the Nobel Prize in Physics for 2013 to

François Englert and Peter Higgs

“for the theoretical discovery of a mechanism that contributes to our understanding of the origin of mass of subatomic particles, and which recently was confirmed through the discovery of the predicted fundamental particle, by the ATLAS and CMS experiments at CERN’s Large Hadron Collider”

Entrance of the Higgs into PDG

H^0 (Higgs Boson)

The observed signal is called a Higgs Boson in the following, although its detailed properties and in particular the role that the new particle plays in the context of electroweak symmetry breaking need to be further clarified. The signal was discovered in searches for a Standard Model (SM)-like Higgs. See the following section for mass limits obtained from those searches.

H⁰

How we can recognize spin?

spin 0

spin 1

spin 2

Spin-0 decays in all directions with equal probability; spin-1 prefers decaying toward or away from the direction of spin; spin-2 prefers the poles and the equator to the region in between. These pictures exaggerate the real distributions for clarity.

Spin observables for $H \rightarrow \gamma\gamma$

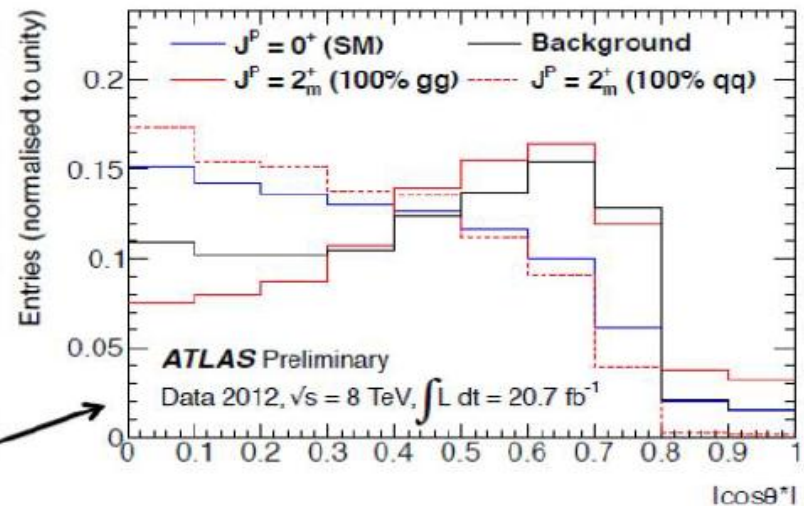

Separate 0^+ and 2^+ spin hypotheses using the angular correlation of the two photons

Relative p_T cuts on the photons remove most correlation with $m_{\gamma\gamma}$
 $qq \rightarrow 2^+$ very similar to SM $gg \rightarrow 0^+$

Collins-Soper frame used to get reference axis z' for $\cos(\theta^*)$

- z -axis bisects angle between the momenta of colliding hadrons
- Minimizes impact of ISR
- Better 0^+ / 2^+ discrimination

Spin study with $H \rightarrow 4l$

- SM predicts $J^{PC} = 0^{++}$
- Angular distributions sensitive to J^P
- Wide range of alternative quantum numbers excluded at $>99\%$ CL
- All observations consistent with expectations for the SM Higgs boson

Tests of
alternative J^P
hypotheses in ZZ

Higgs boson decay width

$$m_h = 125 \text{ GeV} \rightarrow \Gamma_h = 4.07 \text{ MeV}$$

$$\tau_h = 1.62 \cdot 10^{-22} \text{ [s]}$$

A deviation would imply a decay to non-SM particles

Differential Higgs production cross-section

$$\frac{d\sigma_{gg \rightarrow H \rightarrow ZZ}}{dm_{ZZ}^2} \sim \frac{g_{ggH}^2 g_{HZZ}^2}{(m_{ZZ}^2 - m_H^2)^2 + m_H^2 \Gamma_H^2}$$

Γ_h cannot be accessed directly (experimental resolution $\sim 1\text{-}2 \text{ GeV}$)

Indirect measurement

Interference between **A** and **C** : $(A+C)^2 = A^2 + C^2 + 2AC$

tiny \leftarrow \rightarrow *accessible*

Higgs boson decay width

Total width

- Lower bound on total width from decay measurements
- Direct experimental measurements probe 3 orders of magnitude larger than SM width ($\Gamma=4$ MeV)
- Indirect constraint* on the width via measurement of ratio of off-peak to on-peak cross-section
 - CMS: $\Gamma < 13$ MeV
 - ATLAS: $\Gamma < 22$ MeV

*N. Kauer and G. Passarino, JHEP (2012) 2012: 116
 *F. Caola and K. Melnikov, PRD88 (2013) 054024

Couplings: kappa-framework

Scale factor for each (fundamental) coupling:

$$\sigma(i \rightarrow h \rightarrow f) = \kappa_i^2 \sigma_i^{SM} \frac{\kappa_f^2 \Gamma_f^{SM}}{\kappa_h^2 \Gamma_h^{SM}}$$

$$\begin{aligned} \mathcal{L} = & \kappa_3 \frac{m_H^2}{2v} H^3 + \kappa_Z \frac{m_Z^2}{v} Z_\mu Z^\mu H + \kappa_W \frac{2m_W^2}{v} W_\mu^+ W^{-\mu} H \\ & + \kappa_g \frac{\alpha_s}{12\pi v} G_{\mu\nu}^a G^{a\mu\nu} H + \kappa_\gamma \frac{\alpha}{2\pi v} A_{\mu\nu} A^{\mu\nu} H + \kappa_{Z\gamma} \frac{\alpha}{\pi v} A_{\mu\nu} Z^{\mu\nu} H \\ & - \left(\kappa_t \sum_{f=u,c,t} \frac{m_f}{v} f\bar{f} + \kappa_b \sum_{f=d,s,b} \frac{m_f}{v} f\bar{f} + \kappa_\tau \sum_{f=e,\mu,\tau} \frac{m_f}{v} f\bar{f} \right) H \end{aligned}$$

Scale Higgs boson couplings (wrt SM): production & decay

$$\mathcal{L} = \kappa_3 \frac{m_H^2}{2v} H^3 + \kappa_Z \frac{m_Z^2}{v} Z_\mu Z^\mu H + \kappa_W \frac{2m_W^2}{v} W_\mu^+ W^{-\mu} H$$

$$+ \kappa_g \frac{\alpha_s}{12\pi v} G_{\mu\nu}^a G^{a\mu\nu} H + \kappa_\gamma \frac{\alpha}{2\pi v} A_{\mu\nu} A^{\mu\nu} H + \kappa_{Z\gamma} \frac{\alpha}{\pi v} A_{\mu\nu} Z^{\mu\nu} H$$

$$+ \left(\kappa_t \sum_{f=u,c,t} \frac{m_f}{v} f\bar{f} + \kappa_b \sum_{f=d,s,b} \frac{m_f}{v} f\bar{f} + \kappa_\tau \sum_{f=e,\mu,\tau} \frac{m_f}{v} f\bar{f} \right) H$$

$$\kappa_g^2 \propto 1.06\kappa_t^2 - 0.07\kappa_t\kappa_b + 0.01\kappa_b^2$$

$$\kappa_\gamma^2 \propto 1.59\kappa_W^2 - 0.66\kappa_W\kappa_t + 0.07\kappa_t^2$$

What do we measure?

We measure event yields

We want to derive couplings and signal strengths

The first thing we want to measure is the the "signal strength" per channel

The analysis is using discriminators (usually reconstructed mass related) to increase S/B

$$n_s^i = \mu^i \times \sum_p (\sigma^p \times Br^i)_{SM} \times A_p^i \times \epsilon_p^i \times Lumi$$

$p \in (ggF, VBF, VH, ttH) \quad i \in (\gamma\gamma, ZZ, WW, bb, \tau\tau)$

$$\mu^{ZZ}(@125.5 \text{ GeV}) = 1.44^{+0.40}_{-0.35}$$

6.6 σ (4.4 exp) ATLAS

$$\mu^{ZZ}(@125.6 \text{ GeV}) = 0.93^{+0.26+0.13}_{-0.23-0.09}$$

The global signal strength

- Assuming SM ratios of production cross-sections and decay rates

$$\mu = 1.09^{+0.11}_{-0.10}$$

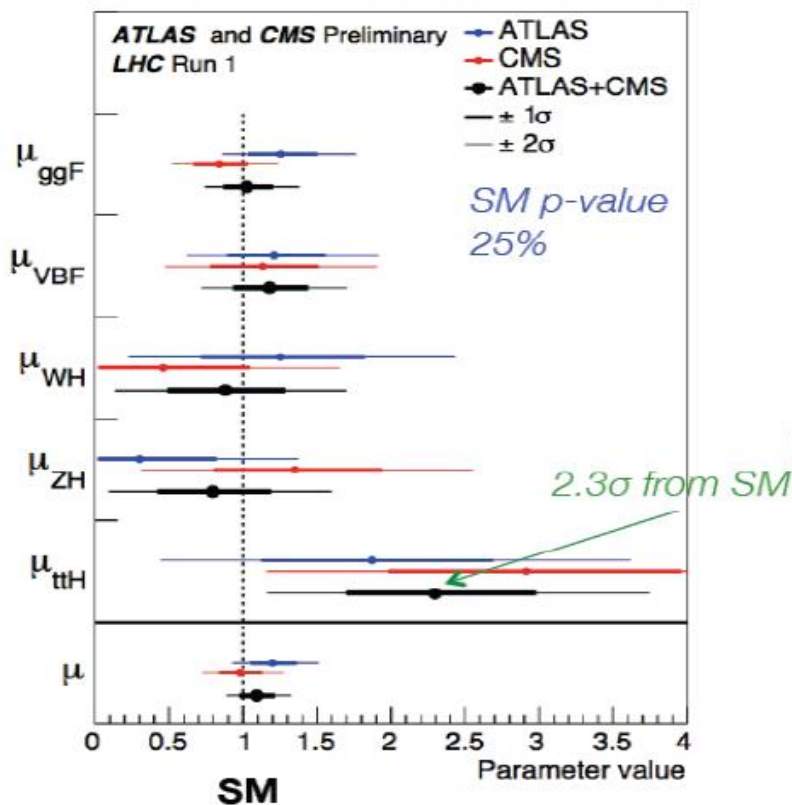

Most precise result at the expense of the largest assumptions

$$= 1.09^{+0.07}_{-0.07} \text{ (stat)} \quad ^{+0.04}_{-0.04} \text{ (expt)} \quad ^{+0.03}_{-0.03} \text{ (thbgd)} \quad ^{+0.07}_{-0.06} \text{ (thsig)}$$

*Stat and Th.Sig of comparable size
(Th.Sig dominated by ggF cross-section uncertainty)*

Signal strength by production and decay mode

Production signal strengths
(SM values of BRs assumed)

Decay signal strengths
(SM value of production σ 's assumed)

Constraints on three-level Higgs couplings

- Assume only SM physics in loops, no invisible or unseen BSM Higgs decays
- Fit for scaling parameters for Higgs couplings to W, Z, b, t, τ , μ

Concluding Higgs couplings measurements

ATLAS and CMS Higgs boson coupling results have been combined, **sensitivity on signal strength improved by almost $\sqrt{2}$**

- **Higgs to $\tau\tau$ and VBF production established at more than 5σ level**
- The most precise results on Higgs production and decay and constraints on its couplings have been obtained at $O(10\%)$ precision.
- Different parametrisations have been studied, all consistent with the SM predictions within uncertainties
- **SM p-value of all combined fits in range of 10%-88%**

What do we know from Run I

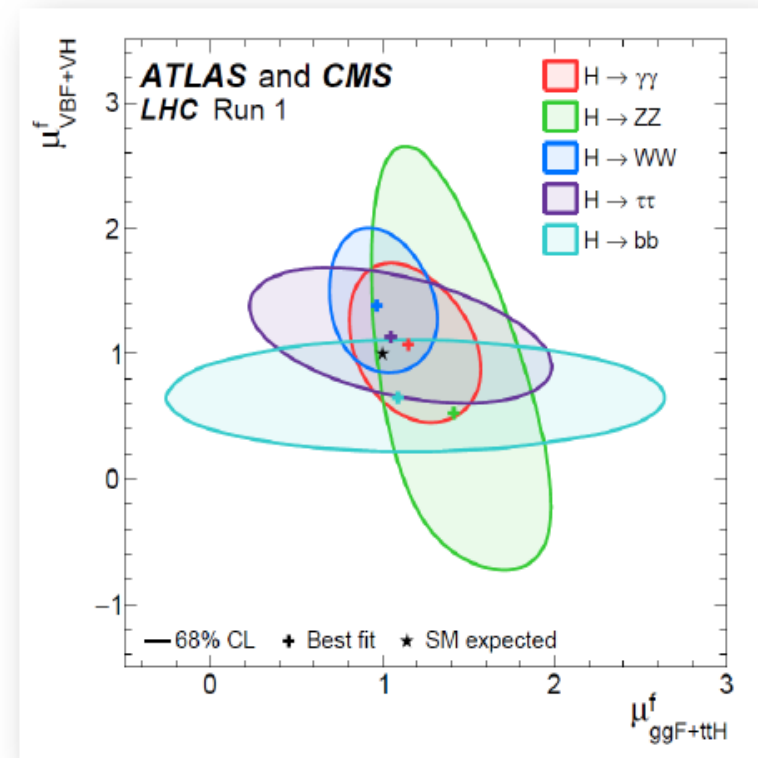

- Discovery of a new neutral scalar boson, first in diboson, then in di-fermion decays

- Observations:

- $H \rightarrow \gamma\gamma$, $H \rightarrow ZZ \rightarrow 4l$
- $H \rightarrow WW \rightarrow 2l2\nu$
- $H \rightarrow \tau\tau$
- gg-fusion and VBF production
- Evidence for VH and ttH processes

- Individual and combined ATLAS and CMS measurements include

- Mass and width
- Production rate (@10% accuracy)
- Decays
- Spin, parity $J^{PC} = 0^{++}$

- Initial compatibility with the Standard Model Higgs

Probing rare Higgs decays

- Exploit growing LHC dataset to explore further decay channels
 - $H \rightarrow \mu\mu$: $2.8 \times SM$
 - $H \rightarrow Z\gamma$: $6.6 \times SM$
 - $H \rightarrow c\bar{c}$:
 - $110 \times SM$ ($ZH(cc)$)
 - $200 \times SM$ ($J/\psi\gamma$)
 - $H \rightarrow \varphi\gamma$: $200 \times SM$
 - $H \rightarrow \rho\gamma$: $50 \times SM$

The Higgs and the LHC

LHC / HL-LHC Plan

First beam in ATLAS (2009)

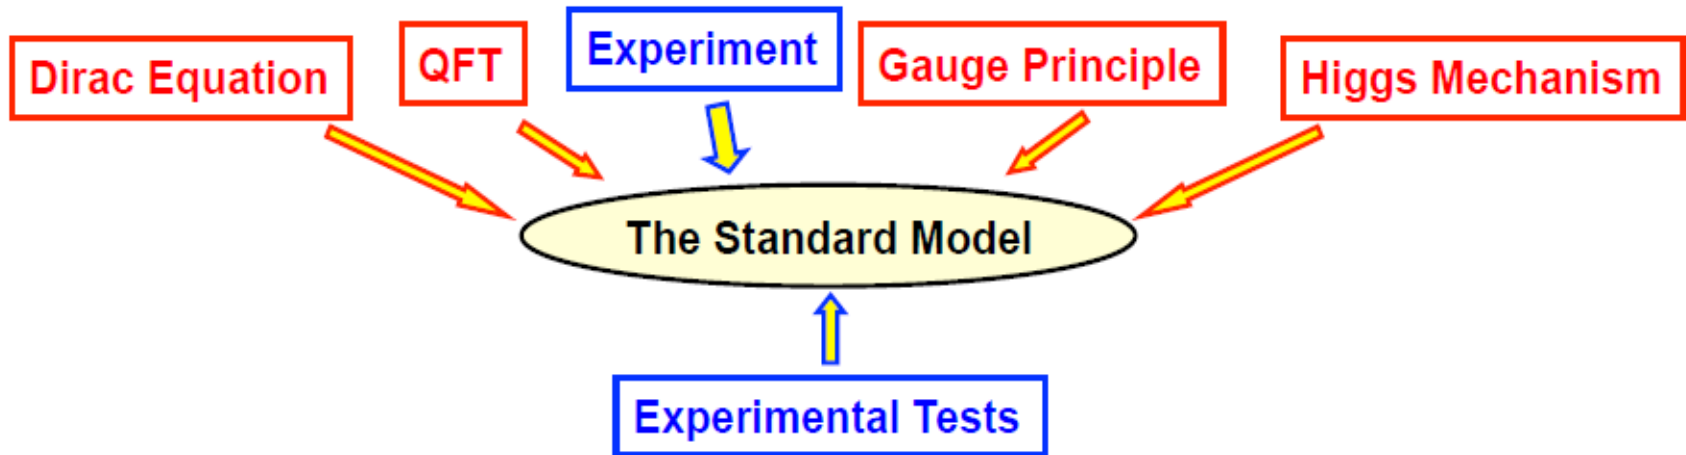

Higgs discovery (2012)

Only ~5% of total expected data

Summary

- ★ The Standard Model of Particle Physics is one of the great scientific triumphs of the late 20th century
- ★ Developed through close interplay of experiment and theory

- ★ Modern experimental particle physics provides many precise measurements. and the **Standard Model** **successfully describes all current data !**
- ★ Despite its great success, we should not forget that it is just a model; a collection of beautiful theoretical ideas cobbled together to fit with experimental data.
- ★ There are many issues / open questions...
